## No. 28.—WOODS OF MALAY.—FROM SINGAPORE.

This collection consists of about one hundred specimens, many having no labels; those marked are as follows:—

- |                     |                    |                        |                  |
|---------------------|--------------------|------------------------|------------------|
| 1. Angasah.         | 9. Kayau Arang.    | 17. Leban.             | 25. Peragah.     |
| 2. Biliang.         | 10. Kamuning.      | 18. Meqbon.            | 26. Rangas.      |
| 3. " Wangi.         | 11. Krautal.       | 19. Medansi Minak.     | 27. Simpoh Ryah. |
| 4. Bras Bras.       | 12. Aranj.         | 20. " Buah Yeah.       | 28. " trekit.    |
| 5. Bitangor wood.   | 13. " Klat.        | 21. " Tandoh.          | 29. Slumar.      |
| 6. Changia.         | 14. Kayu Brompong. | 22. Medansi Kitahanan. | 30. Taupang.     |
| 7. Glam.            | 15. Kledang.       | 23. " Konit.           | 31. Tamping.     |
| 8. Gambu-ayer-ntan. | 16. Laksh wood.    | 24. Polai wood.        | 32. Timbusu.     |

Of these the "Bintangor" wood is the most used, especially in ship-building, serving for planks, masts, spars, &c.; it grows in the greatest abundance round Singapore, and is largely exported to the Mauritius, California, &c. The "Glam" tree furnishes a paper-like bark, used

in caulking the seams of vessels. The wood of the "Polai" tree, which is used to make floats for fishing-nets, is a very remarkable light white wood, and might probably be imported, and used with advantage as a substitute for cork, and some similar substances.

#### No. 29.—WOODS OF PRINCE OF WALES ISLAND.

These are all stated to be furniture woods:—

- |                              |                         |                  |
|------------------------------|-------------------------|------------------|
| 1. Angsena, or Senna Baymah. | 8. Cocoa-nut tree root. | 15. Mirlimoh.    |
| 2. Balah Bungah.             | 9. Durium (wild).       | 16. Penang wood. |
| 3. Balach.                   | 10. Eboch-tree root.    | 17. Ranggas.     |
| 4. Baloh.                    | 11. Ebony.              | 18. Siam wood.   |
| 5. Baloh Bungah.             | 12. Guava wood.         | 19. Timbusi.     |
| 6. Betol-nut tree root.      | 13. Ibool wood.         |                  |
| 7. Clove tree.               | 14. Kamuning.           |                  |

#### No. 30.—WOODS OF PENANG (Col. FRITH).

| NAME.                | Colour.     | Specific Gravity. | REMARKS.  |
|----------------------|-------------|-------------------|---|
| 1. Brantey           | Light brown | —                 | An inferior weak wood; used for building.   |
| 2. Bunho             | "           | —                 | A large tree; occasionally used for building.   |
| 3. Bintagon          | "           | —                 | used for masts.   |
| 4. Curupas           | Dark red    | —                 | Used for beams of houses.   |
| 5. Cooran            | Light brown | —                 | Used for planks for building.   |
| 6. Chiujeritt        | Brown       | 1.165             | A small tree; used for furniture.   |
| 7. Cumpas            | Light brown | —                 | A large tree; used only for planks.   |
| 8. Cawa-Arang        | Pale brown  | —                 | A very large tree; used for furniture and ornamental work.  |
| 9. Canis             | "           | —                 | used for door-frames.   |
| 10. Chiuarcy         | Brown       | 1.081             | Used for beams; does not work kindly.   |
| 11. Cawa-Arang       | Light brown | —                 | Only used for furniture.  |
| 12. Cocoa-nut        | Brown       | —                 | Cut perpendicularly.  |
| 13. China red wood   | Red         | —                 | Only used for furniture.  |
| 14. Ceylon ebony     | Black       | —                 | Used for inlaying and ornamental furniture.   |
| 15. Damarlout        | Brown       | —                 | Used for building and general purposes.   |
| 16. Dunorhung        | "           | 1.235             | Used by the Chinese for carved images.  |
| 17. Dram             | Light brown | —                 | A very small tree; used for ornamental furniture.   |
| 18. Hama Raja        | "           | —                 | little used.  |
| 19. Maddang Kamenhir | "           | —                 | Used by the Chinese for inlaid boxes.   |
| 20. Mirabau          | Light red   | —                 | Much used for ship-building, furniture, &c.   |
| 21. Maddang Tandack  | Dark brown  | —                 | Not used at all.  |
| 22. Maskaw           | Light brown | 1.016             | Used for palankeens, carriages, furniture, &c.  |
| 23. Mankudu          | Brown       | —                 | A species of Damarlout; much used for beams.  |
| 24. Maliler          | White       | —                 | A small tree; used for work-boxes and ornamental work.  |
| 25. Maribot          | Purple      | 0.939             | A very large tree, difficult to work; used for furniture.   |
| 26. Mandara          | Pale red    | 0.939             | A small tree; used for ornamental furniture.  |
| 27. Nebong           | Dark        | —                 | A tall and thin, but straight tree; used for railings.  |
| 28. Papisrang        | Pale brown  | —                 | Six to nine feet in circumference, forty feet long; not good for beams; chiefly used for furniture. |
| 29. Pasa Linga       | Light brown | —                 | A large tree; used only for planks; soon decays.  |
| 30. Pala             | "           | —                 | A tall thin tree; used for planks.  |
| 31. Pinang Back      | Brown       | —                 | A large tree; used for beams.   |
| 32. Pala Utan        | Light brown | —                 | only used for planks.   |
| 33. Papisrang        | Purple      | —                 | A strong wood; used for beams.  |
| 34. Penang teak      | Brown       | —                 | A scarce tree now.  |
| 35. Jack             | Yellow      | —                 | Used only for ornamental furniture.   |
| 36. Bangha-as        | Light brown | —                 | Used for furniture.   |
| 37. Rokam            | Light red   | —                 | Used for boxes and furniture.   |
| 38. Red wood         | Red         | 1.000             | In general use for furniture.   |
| 39. Sankuang         | Pale brown  | —                 | Used only for ornamental work.  |
| 40. Satin wood       | Straw       | —                 | A beautiful wood for ornamental furniture, &c.  |
| 41. Siam ebony       | Black       | —                 | Used only for ornamental furniture, inlaying, &c.   |
| 42. Teak             | Brown       | —                 | In general use.   |
| 43. Tampinnis        | Light red   | —                 | A fruit-tree; used for ornamental furniture, billiard-cues, &c.                                     |
| 44. Tija             | Light brown | —                 | Used for furniture, boxes, &c.  |
| 45. (No name)        | Purple      | —                 | Not durable; used for all sorts of rough work.  |

#### No. 31.—WOODS OF THE INDIAN ARCHIPELAGO.

Extensive collections of woods from Borneo, New Guinea, and several other of the Archipelago Islands, are contributed; including sandal-wood from Timor, and Lingoa, or Amboyna wood, from Ceram, in the Moluccas. This wood, which is very durable, and takes a high polish, was imported from the Moluccas in considerable quantities at the time when the latter were British possessions; it is very abundant, and may be had in any quantity. Very large circular sections are obtained from the lower part of the tree by taking advantage of the spurs, or lateral growths: they are sometimes as large as nine feet in diameter. A circular disc of wood thus obtained,

nearly seven feet in diameter, as well as some other specimens, are exhibited by Messrs. ALMEIDA (p. 891), of Singapore, and were deemed deserving of a Prize Medal by the Jury. Specimens are also shown of the "Kayu-Buka," which is brought from Ceram, New Guinea, Arru, and the other islands of the Moluccas, to Singapore; it is a knotty excrescence, which forms on the stems of the Lingoa tree, and is much esteemed as a fancy wood for cabinet-work; of late years its estimation seems to have decreased in Europe, but it is still much valued by the Chinese. The following is a list of the woods from Labuan:—

|     | NAME.                | Height.   | Diameter. | REMARKS.                         |
|-----|----------------------|-----------|-----------|----------------------------------|
|     |                      | Feet.     | Feet.     |                                  |
| 1.  | Dadarru - - - -      | 80        | 2         |                                  |
| 2.  | Gabar Buto - - -     | about 60  | 3         |                                  |
| 3.  | Jati china - - -     | 60        | 1½        |                                  |
| 4.  | Kalim pupa tapdok -  | 12 to 15  | 1½        |                                  |
| 5.  | Kayu Aru - - - -     | about 60  | 3         |                                  |
| 6.  | Arang - - - - -      | -         | -         | Grows to a large size in Borneo. |
| 7.  | Arru - - - - -       | 30        | 2         |                                  |
| 8.  | Benatore hukit - -   | 70        | 3         |                                  |
| 9.  | Bencoola - - - -     | about 60  | 3         |                                  |
| 10. | Badakutan - - - -    | -         | -         | A fruit tree.                    |
| 11. | Bidarru - - - - -    | 30        | 1½        | A scented tree.                  |
| 12. | Impas - - - - -      | 40        | 2½        |                                  |
| 13. | Gading - - - - -     | 25 to 30  | 1         |                                  |
| 14. | Jamber - - - - -     | 30        | 2         |                                  |
| 15. | Kandis Dahan - - -   | 30        | 2         | A fruit tree.                    |
| 16. | Kalam Pappa - - -    | 30        | 2         |                                  |
| 17. | Karye - - - - -      | 30        | 1½        |                                  |
| 18. | Kapur Rangin - - -   | 90 to 100 | 4 to 5    |                                  |
| 19. | Kuing - - - - -      | 70        | 3         |                                  |
| 20. | Kapur - - - - -      | 90 to 120 | 5         |                                  |
| 21. | Koningutan - - - -   | 40        | 2½        |                                  |
| 22. | Kamuning - - - - -   | -         | 0½        |                                  |
| 23. | Limau - - - - -      | -         | 0½        |                                  |
| 24. | Laoh - - - - -       | -         | -         | Small tree.                      |
| 25. | Leda Karbau - - - -  | about 60  | 3         |                                  |
| 26. | Malam - - - - -      | -         | 3         |                                  |
| 27. | Nasi, Nasi - - - -   | 40        | 2         |                                  |
| 28. | Oobah - - - - -      | 40        | 1½        | Bark used to dye red.            |
| 29. | Plye (root) - - - -  | -         | -         |                                  |
| 30. | Palah palawan - - -  | 30        | 1½        |                                  |
| 31. | Petong - - - - -     | 30        | 1½        |                                  |
| 32. | Rsak - - - - -       | 40        | 2½        |                                  |
| 33. | Rangas - - - - -     | 30        | 1½        | Used for common furniture.       |
| 34. | Sampilou - - - - -   | 60        | 1½        |                                  |
| 35. | Senang adnambukit -  | 90        | 4         | The fruit yields an oil.         |
| 36. | Samuck - - - - -     | 30        | 2         | Used for dyeing.                 |
| 37. | Senang Awan - - - -  | 90 to 120 | 5 to 6    |                                  |
| 38. | Sarogan - - - - -    | 25        | 1         |                                  |
| 39. | Tampui pyah - - - -  | -         | -         | A fruit tree.                    |
| 40. | Tioro - - - - -      | 30 to 35  | 3         |                                  |
| 41. | Tobah tobahutan - -  | 30        | 3         |                                  |
| 42. | Taratang - - - - -   | 20 to 30  | 2         |                                  |
| 43. | Urat Mata - - - - -  | 90 to 100 | 3 to 4    |                                  |
| 44. | Madung sisik - - - - | 50        | 2½        |                                  |
| 45. | Iada - - - - -       | 30        | 2         |                                  |
| 46. | Nibong binar - - - - | 90        | -         | A species of palm.               |
| 47. | subarani - - - - -   | 90        | -         | " "                              |
| 48. | Samala - - - - -     | 50        | 2½        |                                  |
| 49. | Saryuh - - - - -     | 50        | 3         |                                  |

Although, in the preceding lists of woods exhibited by the Honourable East India Company, some of the woods are enumerated more than once, being contributed from different localities; yet, taken as a whole, the entire collection is of the highest interest and importance. As many of the specimens sent over are of a large size, means will be afforded of ascertaining the density, elasticity, strength, and other properties of the several woods,

and thus much valuable practical information may be obtained.

A collection of forty-eight specimens of woods from Ceylon is exhibited in the Colonial Department, consisting of timbers used in house-building, and for purposes of construction, and of ornamental or furniture woods. The following is a list of these woods:—

#### WOODS OF CEYLON.

1. Ahoo (19) - - - - A soft, though fine, but not very close-grained, light wood.
2. Alooboa (39) - - - A rather soft, coarse, open-grained, but not very light wood.
3. Cahamille (66) - - - A very hard, fine, close, even-grained, heavy wood.
4. Calamander (2) - - - An exceedingly hard, fine, close-grained, heavy wood, of a pale-reddish hue; with the heart and isolated elongate patches of an intense black. This specimen is inscribed at the back "Hoamidina."
5. Ceylon Teak (61) - - A rather hard, fine, close-grained, and somewhat heavy wood.
6. Cochin Teak (70) - - A rather hard, though somewhat coarse and open-grained, moderately heavy wood, of a lighter hue, rather coarser texture, and considerably more ponderous than the Moulmein teak.
7. Cocos-nut (75).
8. Domba (83) - - - - A soft, coarse, open-grained, light wood, bearing a strong resemblance to inferior Honduras mahogany, takes a good polish, and presents a pretty curled pattern; but judging from this specimen, which is much worm-eaten, it cannot be a very durable wood, at all events in its native country.
9. Drapora (31) - - - A hard, fine, rather close-grained, somewhat heavy wood.
10. Ebony - - - - - A beautiful specimen of a well-known wood.
11. Flower Batten (76) - - A very hard, fine, close-grained, heavy wood. Its polished surface shows a pleasing mottled pattern.
12. Galmendra (68) - - - A rather hard, very fine, but not close-grained, heavy wood.
13. Gedepora (25) - - - A rather hard, fine, close-grained, heavy wood.
14. Goorkiasna (14) - - - A soft, fine, but open-grained, light wood.
15. Hadwicks (36) - - - A moderately hard, fine, close-grained, rather heavy wood.

## WOODS OF CEYLON—continued.

16. Hall (28) - - - A very soft, coarse, open-grained, light wood, evidently adapted only for very inferior work, and where durability is not required.
17. Halmendora (67) - - - A hard, fine, close-grained, heavy wood.
18. Halmille (43) - - - A rather soft, though fine, but not very close-grained, heavy wood.
19. Hampalede (36) - - - A rather soft, fine, though open-grained, heavy wood.
20. Hick (57) - - - A very hard, fine, close, very uniformly-grained, heavy wood, in colour resembling pencil-cedar.
21. Horre (74) - - - A hard, though coarse, open-grained, heavy wood.
22. Houcklerier (15) - - - A soft, fine, but open-grained, rather heavy wood.
23. Kadoll (13) - - - A rather hard, fine, close-grained, heavy wood. Specimen much worm-eaten.
24. Kadombairia (3) - - - A rather hard, fine, close-grained, somewhat light wood; its surface curiously veined.
25. Kadoomba (42) - - - A soft, though fine, close-grained, and rather light wood.
26. Kattukende (27) - - - A hard, fine, rather close-grained, heavy wood.
27. Kirepalle (25) - - - A very soft, coarse, open-grained, light wood.
28. Koon (12) - - - A very hard, fine, close-grained, heavy wood.
29. Koesor Jack (6) - - - A moderately hard, but rather coarse and open-grained, though heavy wood, of a beautiful saffron yellow colour; emits a peculiar, but by no means unpleasant odour.
30. Kuretia (29) - - - A hard, fine, close-grained, heavy wood.
31. Meenanmille (60) - - - A very hard, fine, close-grained, heavy wood.
32. Millele (5) - - - Probably specifically identical with Sapoomillile, with which it coincides in every respect. • [Fide No. 43.]
33. Moolmein, Teak (64).
34. Naa (72) - - - A very hard, fine, close-grained, and very ponderous wood.
35. Numede (34) - - - A rather hard, very fine, close-grained, heavy wood.
36. Nondoon (48) - - - Hard, though coarse, open-grained, heavy wood.
37. Obbairia (55) - - - Hard, rather fine, generally close-grained, presenting, however, many open cells; heavy.
38. Palmira (71) - - - A species of palm.
39. Paloo (65) - - - A hard, fine, close-grained, heavy wood: heart-wood deep red-brown, recent layers reddish yellow; its compact, even structure, indicates that it is admirably adapted for turnery work.
40. Patta Dell (62) - - - A soft, coarse, open-grained, light wood.
41. Pelan (54) - - - A very hard, fine, close-grained, heavy wood.
42. Sapbo (53) - - - A soft, fine, but rather open, though even-grained, light wood.
43. Sapoomillile (77) - - - A soft, rather coarse, open-grained, light wood.
44. Sattin (60) - - - A hard, fine, close-grained, heavy wood.
45. Sooriye (73) - - - A hard, though somewhat coarse and open-grained, heavy wood, of a deep chesnut colour.
46. Tamarind (4) - - - An exceedingly hard, fine, close-grained, very heavy wood.
47. Tarine (35) - - - A hard, fine, close-grained, rather heavy wood, much resembling English birch.
48. Wanedile (37) - - - A rather hard, fine, close, even-grained, heavy wood.

## WOODS OF CAPE OF GOOD HOPE, &amp;c.

Several interesting specimens of timber and other woods are contributed from South Africa and the Cape of Good Hope. One specimen in particular deserves special notice; it is called Red Ebony, from Natal, and is contributed by C. J. BUSK (60, p. 952). It is a hard, heavy, very close-grained, red wood, admirably adapted for turning and the finer sorts of cabinet work; approximating in fact, in character, somewhat to ivory. This wood appears to be new, and it is unquestionably a valuable addition to the hard ornamental woods already known; the Jury, accordingly, awarded a Prize Medal for it.

A valuable small collection of the woods of the Cape of Good Hope, is exhibited from the MORAVIAN MISSION at Gnathendal (44, p. 950); it consists of thirty specimens, and was deemed worthy of Honourable Mention. The annexed table contains a list of these woods, their sizes, and the uses to which they are applied in the colony.—(See Table I., p. 141.)

A second series of Cape woods, including a number not in the Gnathendal Collection, and valuable because the specimens are shown in the bark, is exhibited by H. DUMMLERON of George District (47, p. 951); this was likewise deemed worthy of Honourable Mention. (For list of this series, see Table II., pp. 141, 142.)

A specimen of teak wood, from the Western Coast of Africa, a valuable timber, well known and valued by ship-builders, is shown by WARWICK WESTON (1, p. 952).

## WOODS OF CANADA.

Very remarkable specimens of the chief varieties of Canadian timber are exhibited; especially the collection shown by the CENTRAL COMMISSION of MONTREAL (80, p. 963), for which the Jury awarded a Prize Medal (see p. 8). It includes excellent specimens of the following woods:—

- |                  |                   |                   |
|------------------|-------------------|-------------------|
| 1. Ash, curled.  | 4. Pine wood.     | 7. Elm, red rock. |
| 2. Birch, white. | 5. Cedar, pencil. | 8. Iron wood.     |
| 3. Butter-nut.   | 6. Elm.           | 9. Maple, soft.   |

- |                   |                 |                    |
|-------------------|-----------------|--------------------|
| 10. Maple, hard.  | 13. Oak, white. | 17. Spruce.        |
| 11. " bird's-eye. | 14. Pine, red.  | 18. Tamarack.      |
| 12. Oak, red.     | 15. " yellow.   | 19. Walnut, black. |
|                   | 16. " white.    |                    |

The butter-nut, and black walnut are excellent furniture woods, and hardly seem to be so well known or appreciated as they deserve. Very fine specimens of butter-nut, birch, pine, cherry, curled black walnut, and maple, both curled and bird's-eye, are exhibited by MESSRS. REED and MEAKINS of Montreal (75, p. 963) these were also judged worthy of a Prize Medal by the Jury.

Fine specimens are also shown of curled black walnut by — FISHER, of Simcoe (78, p. 963); of bird's-eye maple, by J. EGAN, of Ottawa (74, p. 963); of black walnut, by J. HANSON, of Dawn (79, p. 963); and of soft maple and chestnut, by J. and F. PARISCAULT, of St. Martin (76 and 77, p. 963). The Jury deemed each of these deserving of Honourable Mention.

Small samples of a few woods from New Brunswick are exhibited; namely, bird's-eye and curly maple, black birch, and the candleberry myrtle.

A few woods are contributed from Nova Scotia; including curled and bird's-eye maple, birch, and white and grey oak.

## WOODS OF BRITISH GUIANA.

A valuable and very interesting collection of timber and other woods from British Guiana, is contributed by several independent exhibitors. The Jury awarded Prize Medals to J. OUTRIDGE (84, 84A, 85, 85A, 85C, 87, 88, 89, 91, 92, 97, 98, 104 to 115, 117D, E, F, G, H, &c., pp. 982, 983, 984, 985); and to J. S. STUCKENBURY (85A, 116, 117A, &c., pp. 982 and 985), for their collections of woods; and they deemed the specimens shown by A. BUCHANAN (86, 90, 95, 96, pp. 982, 983); T. B. DUGGIN (90A, 99, 100, 101, 102, p. 984); T. FAUCET (93, 94, p. 983); G. PONTREUX (102A, p. 984); and J. F. BEE (103, 105, 116, 117, &c., pp. 984, 985), severally deserving of Honourable Mention.

Mr. BEE also exhibits a numerous series of small samples of the chief woods of Guiana (156, p. 987).—See List, pp. 144-146.

TABLE I.—List of 30 Specimens of Woods from the MORAVIAN MISSION, CAPE OF GOOD HOPE.

| NAMES.          | BOTANICAL NAMES.                              | General Height without Branches.<br>Feet. | Diameter.      | QUALITY.                                   | USES.                                       |
|-----------------|---|---|----------------|--|---|
| 1. Alder, red   | <i>Cunonia capensis</i>                       | 15 to 25                                  | 2 to 3 ft.     | Hard and tough                             | Wagon work.                                 |
| 2. Alder, white | <i>Weinmannia trifoliata</i>                  | 10 12                                     | 2 3            | Tough and soft                             | Planks.                                     |
| 3. Ash          | <i>Ekebergia capensis</i>                     | 20  | 1              | Tough                                      | Wagon work.                                 |
| 4. Assagay wood | <i>Curtisia faginea</i>                       | 20 40                                     | 3              | Very tough                                 | Wagon wheels.                               |
| 5. Becc         | <i>Myrsine melanophloeos</i>                  | 15 25                                     | 2              | Tough                                      | Wagon work.                                 |

## WOODS OF BRITISH GUIANA.

- Black greenheart.** [85b, 85c.] Shows a diameter of 11½ inches. In bark. A very hard, fine, close-grained, heavy wood. Duramen deep brown; recent layers narrow, pale-ochre yellow. The timber of this tree is used for ship-building, planks, &c., and is considered more durable than the common green-heart. The specimens sent are from a tree supposed to be about 50 years old.
- Blackheart.** [111, 111a.] - Shows a diameter of 4 inches. In bark. A soft, light wood; from the River Demerara. This is a good wood for house frames, and for making furniture. It will square from 6 to 7 inches, from 20 to 30 feet long.
- Bully-tree, (Mimusops sp.?)** [91, 91a.] Shows a diameter of 12 inches. In bark. A fine close-grained, moderately hard, and rather heavy wood; from the River Demerara. The tree yielding this wood is supposed to be a species of *Mimusops*. It is found throughout the colony, but most abundantly in the county of Berbice. It is of great size, and squares from 20 to 30 inches, and may be obtained from 20 to 30 feet long. The weather has little effect upon it, and it is employed for house-frames, posts, floors, &c. The upper portion of the trunk and branches are manufactured into shingles, wheel-spokes, palings, &c.
- 4. Cabacalli.** [112, 112a.] - Shows a diameter of 4½ inches. In bark. A fine close-grained, moderately hard, and rather heavy wood; from the River Demerara. This wood is impregnated with a bitter principle, which defends it against worms; it lasts well under water, and is much used for plankings colony craft. It must, however, be fastened with copper nails. It will square from 12 to 16 inches, or even more, from 40 to 45 feet long.
- Camara or tonkin-bean (Dipteryx odorata, Willd.)** [95, 95a.] Shows a diameter of 20 inches. In bark. A fine close-grained, hard, and very heavy wood; from the River Essequibo. This wood is obtained from *Dipteryx odorata*, Willd.: the tree which produces the well-known tonkin bean. It is hard, tough, and durable in an eminent degree, and it is said that a portion of its timber, 1 inch square, and of a given length, bears 100 lbs. more weight than any other timber in Guiana of the same dimensions. It is therefore peculiarly well adapted for any purpose, where resistance to great pressure is the object, and for shafts, mill-wheels, or cogs. It will square from 18 to 20 inches, from 40 to 50 feet long. This tree is, however, not very plentiful in this colony.
- 6. Coffee tree (Coffea Arabica).** [116, 116a.] Shows a diameter of 3 inches. A fine, close-grained, hard, heavy wood, of a beautiful cream white throughout, and having the appearance of box, both in structure and growth; from Canal No. 2, River Demerara.
- 7. Cork-wood (Pterocarpus Draco, Linn.; P. suberosus, Pers.)** [102, 102a.] Shows a diameter of 5 inches. In bark. An exceedingly light and soft, though fine even-grained wood; from the River Berbice.
- \*8. Cork-wood.** [102b.] - A curious excrescence, styled in the label "an abutment of the foregoing." In form, very like rough cork; about an inch in thickness throughout, enveloped in a thin hard bark. The wood is much softer than in 102 and 102a, and would doubtless afford an excellent substitute for cork for entomological purposes. From Tootie Island in the River Essequibo. An abutment from near the root of the tree. This wood is supposed to be obtained from *Pterocarpus Draco*, Linn., or *P. suberosus*, Pers., and is chiefly used as floats for fishing-nets.
- Courida (Avicennia nitida, Jac.)** [103, 103a.] Shows a diameter of 5½ inches. In bark. An open-grained, moderately soft, and rather light wood; from Plantation Woodlands, River Mahaica. This wood is obtained from *Avicennia nitida*, Jacq., a tree of surprising rapidity of growth. These specimens are from a tree five years old. The wood is perishable when exposed to the atmosphere, but is very durable under ground, and is, therefore, used in foundations for buildings.
- 10. Coutaballi.** [110, 110a.] - Shows a diameter of 5 inches. In bark. A very fine, close-grained, hard, heavy wood; from the River Demerara. The tree which yields this timber grows upon sand-hills; the wood is very hard and durable, if not exposed to the weather; it is plentiful, and principally used for house-frames, and will square 12 inches, from 30 to 40 feet long.
- 11. Crab-wood (Xylocarpus carapa, Spreng.; Carapa Guianensis, Aubl.)** [108, 108a.] Shows a diameter of 7½ inches. In bark. A tolerably hard, even-grained, rather light wood. In great repute, and largely used in the colony for interior work; from the River Demerara. This wood is obtained from *Xylocarpus carapa*, Spreng., or *Carapa Guianensis*, Aubl., the seeds of which yield the crab-oil. It is a light wood, and takes a high polish, and is used for masts and spars, flooring, partitions, and doors of houses. There are two varieties, the red and white. These specimens are the white. It squares from 14 to 16 inches, from 40 to 60 feet long.
- 12. Determa.** [107, 107a.] - Shows a diameter of 6 inches. In bark. A rather hard, but not very close or even-grained wood. The most valuable of the British Guiana woods for ship-building purposes, where it is used chiefly for the bottoms of vessels; grows to a much larger size than represented in the present specimen; from the River Demerara. This wood is used for masts, booms, and plankings for colonial craft; and as insects do not infest it, it is well adapted for chests, wardrobes, &c. It will square from 14 to 16 inches, from 40 to 60 feet in length.
- 13. Greenheart (Nectandra Rodiei, Benth.)** [85, 85a.] Shows a diameter of 12 inches. In bark. A very hard, heavy, fine, but not even-grained wood. Duramen deep brown, recent layers broad pale yellow; from the River Demerara. The Greenheart tree is very abundant, and its timbers, squaring from 18 to 24 inches, can be procured from 60 to 70 feet long. It is a fine-grained hard wood, well adapted for the planking of vessels, house-frames, wharves, bridges, and other purposes where great strength and durability are required. Mr. Mansfield, engineer of the Demerara Railway, states, that this is the best timber for resisting tensile and compressive strains, and is therefore well adapted for keelsons for ships, and beams.
- 14. Hackia, or Ligdum vitae (Guaiacum officinale, Linn.?)** [98, 98a.] Diameter 15 inches; from the River Demerara. This wood, known in the colony as *lignum vitae*, is said to be obtained from *Guaiacum officinale*, Linn.; but this seems doubtful, as the tree producing the wood attains a height of from 80 to 60 feet, and squares 16 to 18 inches, whilst the *Guaiacum officinale* is described as a comparatively small tree, about 4 or 5 inches in diameter. It is used

## WOODS OF BRITISH GUIANA—continued.

for mill-cogs, and shafts. The specimens sent are from a tree supposed to be about 40 years old.

## 15. Hooboball. [89, 89a.]

Shows a diameter of 15 inches. In bark. A fine close-grained, hard, heavy wood. Duramen deep-red chestnut; alburnum nut brown; from the River Demerara.

This wood is very close and fine-grained, is easily worked, takes a high polish, and is much used in the colony for furniture. It may be had from 15 to 20 inches square, 40 to 70 feet long. The specimens sent are from a tree supposed to be about 20 years old.

## 16. Hyawaball. [117j, 117k.]

Shows a diameter of 8 inches. In bark. A fine, close-grained, hard, heavy wood; from the River Demerara.

This tree is scarce. This wood, known as zebra wood, is used for furniture. The specimens sent are from a tree supposed to be about 25 years old.

17. Hyawa (*Leica heptaphylla*, Aubl.) [10i, 101a.]

Shows a diameter of 5 inches. In bark. A light, though rather fine close-grained white wood; from the River Berbice.

This wood is obtained from the *Leica heptaphylla*, Aubl., or Incense tree, yielding the gum hyawa.

18. Itaball (*Vochysia Guianensis*, Aubl.) [117f, 117g.]

Shows a diameter of 11 inches. In bark. An open-grained, light, and rather soft wood; from the River Demerara.

The tree which produces this wood is *Vochysia Guianensis*, Aubl., and is used by the Indians for making corals.

19. Itikiribouraball. (*Mucharium Schomburgkii*, Benth.?) [104, 104a.]

Shows a diameter of 12 inches. In bark. A close-grained, hard, heavy wood; duramen bright chestnut; alburnum broad, white; from River Demerara.

This wood is supposed to be obtained from *Mucharium Schomburgkii*, Benth. The trunk grows to the length of from 30 to 40 feet, and squares from 12 to 16 inches. It is used chiefly for cabinet-work.

## 20. Kakar Ally. [87, 87a.]

Shows a diameter of 10 inches. In bark. A fine, close, even-grained wood, hard and heavy. Duramen deep red brown, alburnum broad, pale, dirty yellow; from the River Demerara.

This wood is very plentiful, and it has been proved that it is more durable than greenheart in salt water, as it possesses the quality of resisting the depredations of the sea-worm and barnacle. It may be had from 6 to 14 inches square. The specimens sent are supposed to be about 20 years old.

21. Lana (*Gnopa Americana*, Linn.) [99, 99a.]

Shows a diameter of 6 inches. Centre traversed by a longitudinal cylindrical furrow, continuing in transverse section a hard granulated pith. Wood fine, close-grained, moderately hard, rather heavy. Bark bearing a strong resemblance to that of the common birch; from the River Berbice.

This wood is obtained from *Gnopa Americana*, Linn.: the fruit of which yields the Indian pigment known as Lana dye. The tree is very high, and the trunk will frequently square from 14 to 18 inches. The wood is close-grained, and is not liable to split.

## 21\* Kocerettall. [109, 109a.]

Shows a diameter of 13 inches. In bark. A very close-grained, hard, heavy wood; from the River Demerara.

This wood forms excellent rafters, and beams for cottages. It grows from 20 to 30 feet long, and is from 4 to 6 inches in diameter.

22. Letter-wood (*Brosimum Aubletii*, Poep, *Puatineria Guianensis* Aubl.)

Called by the Indians, "Bourra Coura" 20 inches  $\times$  4  $\times$  1½. Fine, close-grained, hard, and rather heavy, a beautiful wood, of a bright-red chestnut colour, with small rhomboidal black patches, mostly isolated, though occasionally concurrent. Used for ornamental purposes, especially for picture-frames; several walking-sticks of this wood, from the colony, are exhibited, vide No. 148; unfortunately, it never attains a large size; from the River Corentyne.

This is obtained from *Brosimum Aubletii*, Poep., or *Puatineria Guianensis*, Aubl., and is one of the costliest woods which Guiana possesses. It is of a beautiful brown colour, with black spots, which have been compared to hieroglyphics; the spotted part being peculiar to the heart, which is seldom more than 12 to 15 inches in circumference. It is adapted for cabinet-work of small size, and for veneering only. From its extreme hardness it is difficult to work, and is therefore little used.

## 23. Marisiball. [117r, 117s.]

Shows a diameter of 8 inches. In bark. An exceedingly close-grained, hard, heavy wood; from the River Demerara.

This tree is plentiful, and is used chiefly for spars. It will square from 13 to 14 inches, from 30 to 40 feet in length. The specimens sent are from a tree supposed to be about 20 years old.

24. Mammee apple-tree (*Mammea Americana*, Linn.) [100, 100a.]

Shows a diameter of 7 inches. A wood very like that of the English pear tree. In bark; from the River Berbice.

This wood is obtained from the *Mammea Americana*, Linn., which produces a Mammee apple, or wild apricot of South America.

25. Mora (*Mora caribea*, Benth.) [84, 84a.]

Shows a diameter of 12 inches. In bark. A hard, heavy, close, but not even-grained wood; from the River Demerara.

The tree producing this wood frequently reaches a height of upwards of 100 feet. It grows abundantly on barren sand-reefs. It is tough, close, and cross-grained, and is peculiarly adapted for ships' timbers and planks, for which purpose it is extensively used. The trunk of this tree, when of the height of from 40 to 50 feet, will square from 18 to 24 inches, but when grown to that size, it is generally faulty. The specimens sent are from a tree supposed to be from 30 to 40 years old.

26. Purpleheart (*Copaifera pubiflora* or *bracteata*). [86, 86a.]

Shows a diameter of 14 inches. In bark. A hard and ponderous, though open-grained wood. Duramen, in longitudinal section, bright claret; in transverse section, deep brown purple; recent layers narrow, pale yellow; from the River Essequibo.

The purpleheart yields a timber possessing great strength, durability, and elasticity, and is described by Dr. Lindley as "invaluable for resisting the shock of artillery discharges," on which account it is employed for mortar beds. It is used for windmill shafts, rollers, and machinery.

## 27. Paka, or Bastard Purpleheart. [117b, 117c.]

Shows a diameter of 11 inches. In bark. A fine, close-grained, hard, heavy wood. Heart-wood bright purple, recent layers narrow, dirty white; in brightness of colour, it exceeds the real Purpleheart; from the River Demerara. Used for furniture.

Not in bark, diameter doubtful, certainly exceeding 18 inches. A coarse, open-grained, hard, heavy wood; from the River Essequibo.

This wood is obtained from *Caryocar tomentosum*, Dec., or *Pekoa tuberculosa*, Aubl., the tree which yields the delicious nut, known as the Saouari, or Searri nut. It greatly

## WOODS OF BRITISH GUIANA—continued.

- resembles in its properties the Mora, being excellent for ship-building, mill-timbers, and plank, and may be had from 10 to 20 inches square, from 20 to 40 feet long.
29. Silverballi, Yellow (*Nectandra* sp. ?) [92, 93a.] A rather soft, open-grained, light wood; from the River Demerara. This wood is supposed to be derived from a species of *Nectandra*. It is light, and floats, and contains a bitter principle, which protects it from the attacks of worms. Hence it is much used for the outside planking of colony craft: it is also used for booms and masts. It grows to a great size, but then it is often hollow. It will, however, square sound from 10 to 14 inches, from 40 to 50 feet long.
30. Silverballi, Brown. [93.] — A fine, close-grained, moderately hard, and rather heavy wood. Portion of the planking of a drogher. This specimen formed part of the outside planking of a drogher, employed in the conveyance of produce in this colony, and is known to have been exposed to the action of salt water during a period of 20 years.
31. Silverballi, Brown. [94.] — Although bearing a similar label to the foregoing, its specific identity therewith is doubtful; it differs in colour, is more open-grained, and much lighter. It is, however, possible that this specimen may represent the alburnum, and not the duramen of the same tree; if so, it must attain a very large size. Portion of the planking of a punt. This specimen formed part of the bottom of a punt, known to have been used in the Demerara River for a period of 30 years and upwards. Shows a diameter of 7 inches. In bark. A fine, close-grained, moderately hard, and rather heavy wood; bark smooth, much resembling that of common beech; from the River Demerara. This wood is used for furniture. The specimens sent are from a tree supposed to be about 20 years old.
32. Simiri, or Locust tree (*Hymenaea Courbaril*, L.) [117n, 117o.] Shows a diameter of 1½ inches. In bark. A rather open-grained, though hard, heavy wood; from the River Demerara. The tree producing this wood is *Hymenaea Courbaril*, Linn., and is plentiful in various parts of the colony. It often attains a height of from 60 to 80 feet, with a trunk from 7 to 8 feet in diameter. The wood is hard and compact, and its durability recommends it for mill-rollers and similar purposes. The Indians make "woodskins" out of the bark. The specimens sent are from a tree supposed to be about 100 years old. Shows a diameter of 9 inches. In bark. A moderately hard, rather heavy, but not even-grained wood. Alburnum not perceptibly lighter in colour than the duramen; from the River Demerara. It is much used for timbers, rails, and covering boards for colony craft, and for naves and felloes of wheels; it is also made into canoes by the Indians. It will square from 14 to 18 inches, from 30 to 40 feet long.
34. Tacouba, or Heart of Wallaba. [90b.] From the River Berbice. This wood is the heart of the upper portion of the trunks of Wallaba trees which have been felled in the forests, and from which the sapwood has decayed. These are much used as paling-posts, and for other out-door purposes, being found to be so durable as to be almost imperishable. They are about to be used as sleepers on the Demerara Railway, for which purpose it is supposed they will prove to be peculiarly well adapted. The defect of Wallaba and of its Tacouba, is its inability to bear great lateral strain; it should not, therefore, be used for beams longer than 12 feet.
35. Tiger-wood. [117, 117a.] 8½ inch × 5 inch × 2 inch. Shows heart-wood only. A fine, close, even-grained, very hard, and ponderous wood, of a bright red chestnut colour, remarkable for its isolated lunate black spots, which, however, sometimes assume an irregular form; susceptible of a high polish; from the River Demerara. In the printed Catalogue accompanying the collection, this wood is stated to be the "heart-wood of the Iikiribounaballi," on comparing it with the specimens of the latter, Nos. 104, and 104a, it is manifest that the two woods are totally distinct. Mr. Bee, to whom the circumstance was pointed out, confirmed this fact, observing that the specimens of Tiger-wood now under consideration were cut from a tree undoubtedly specifically distinct from that which yields the Iikiribounaballi.
36. Too Roo. [115, 115a.] A species of palm; from the River Demerara. It grows to the height of from 50 to 70 feet. Its woody outside is used by the cabinet-makers for inlaid work, walking-sticks, billiard-cues, &c.
37. Torch-wood. [114.] — Supposed to be obtained from a species of *Imyrice*, or *Icica*. When beaten so as to separate the fibres, the branches are used as torches by the Indians.
38. Towraneroo, or Bastard Bully tree. [117p, 117q.] Shows a diameter of 10 inches. In bark. A fine, close, even-grained, hard, heavy wood; from the River Demerara. It is very plentiful, and is used for framing-timber, spokes, &c. It will square 25 inches, from 40 to 50 feet long. The specimens sent are from a tree supposed to be about 50 years old.
39. Waladuri, or Monkey-pot tree (*Lecythis grandiflora*, Aubl.) [117h, 117i.] Shows a diameter of 10 inches. In bark. A close-grained, tolerably hard, and heavy wood, presenting, however, numerous open cells; heart-wood bright amber yellow, recent layers narrow, white; from the River Demerara. The tree which produces this timber, is the *Lecythis grandiflora*, Aubl., and is plentiful. The wood is used for furniture, staves, &c. The specimens sent are from a tree supposed to be about 25 years old.
40. Wamara, or brown ebony. [88, 88a.] Shows a diameter of 12 inches. In bark. A remarkably fine, close-grained, hard, heavy wood. Heart-wood of a beautiful deep sandy-brown; recent layers broad (3 inches), dirty yellow. From the River Demerara. This wood is hard and cross-grained, consequently not apt to split; it would, therefore, answer various purposes in naval architecture. It may be had from 6 to 12 inches square, and from 40 to 60 feet long. The Indians make war-clubs of it. The specimens sent are from a tree supposed to be about 20 years old.
41. Wallaba (*Eperua falcata*, Aubl.) [90, 90a.] Shows a diameter of 9 inches. In bark. Wood hard and heavy, though rather open-grained. Duramen bright red-brown; recent layers narrow, pale reddish-yellow. From the River Essequibo. This wood is produced from a tree very abundant throughout the colony. It is hard, splits freely, and is very durable from being impregnated with a resinous oil. It is used for house-frames, palings, shingles, staves, &c. It has been ascertained that a roof well shingled with this wood will last upwards of 40 years. It may be had from 15 to 20 inches square, from 30 to 40 feet long.

## WOODS OF BRITISH GULANA—continued.

42. Warracoeri, or white cedar (*Teca altissima*, Aubl.) [105, 105a, 105b, 105c.] Shows a diameter of 7 inches. In bark. An open-grained, soft, light, white wood; from River Demerara, and from River Mahaica, east sea coast, Demerara. This wood is obtained from *Teca altissima*, Aubl. It is light, easily worked, and very aromatic. Sir Robert Schomburgk states that one of his canoes, 42 feet long and 5 feet wide, was made from a tree of this species. It is used for oars and paddles, and for boards for inside work of houses. During the American war it was used for staves of sugar hogsheads.
43. Yaruri, or paddle-wood (*Aspidosperma excelsum*, Benth.) [97, 97a, 97b.] In bark. A very hard, close-grained, light wood, of eccentric growth; from the River Demerara. This wood is obtained from *Aspidosperma excelsum*, Benth. The whole tree, from 5 to 6 feet in diameter, and to the first branches, about 50 feet in height, has the appearance of being fluted, or as if it consisted of a fasciculus of numerous slender trees. The fluted projections of the trunk are used by the Indians for the construction of their paddles. The wood is light, elastic, and very strong, and preferred to any other for cotton gin-rollers.
44. Yarri-yarri, or Lance-wood (*Thugetia quitarensis*, Lindl.) [113, 113a.] Specimen affording no clue to diameter. A light, yet fine, close-grained, and tolerably hard wood; from the River Demerara. This tree is stated by Schomburgk to be *Thugetia quitarensis*, Lindl., a slender tree found in tolerable abundance in the interior of the colony. The wood possesses much toughness and elasticity, and is used for gig-shafts, and when small, for whip-handles and fishing-rods. The Indians make their arrow-points of it. It grows from 4 to 6 inches diameter at the lower end, and from 15 to 20 feet long.

A table made of the ornamental woods of Guiana, and containing 82 different woods, is also exhibited; the specimens being of course small, and covered with varnish, it is not possible to identify more than a very few of them; the following is a list of them, and contains a large number not mentioned in the preceding list of larger specimens:—

|                       |                                     |                        |                         |
|-----------------------|-------------------------------------|------------------------|-------------------------|
| 1. Armiosl.           | 22. Determa                         | 42. Kurahara.          | 63. Saka.               |
| 2. Assepoca.          | 23. Duralli                         | 43. Kinnasumasa.       | 64. Sirdani.            |
| 3. Akvaka.            | 24. Gomairow.                       | 44. Kurahara.          | 65. Silberdani.         |
| 4. Arawica.           | 25. Guava                           | 45. Kurawara.          | 66. Tumballi.           |
| 5. Acouib root        | 26. Givcheart                       | 46. Koyasa.            | 67. Tatabo.             |
| 6. Brown silverballi. | 27. Hawassa                         | 47. Lana.              | 68. Tabicushi.          |
| 7. Bannia             | 28. Hynakusi                        | 48. Looust             | 69. Towancouo.          |
| 8. Bartaballi         | 29. Hoooboballi.                    | 49. Logwood.           | 70. White cedar.        |
| 9. Bangro, or ebony.  | 30. Hyawabali                       | 50. Letter wood.       | 71. Waiki.              |
| 10. Bully tree        | 31. Huballi                         | 51. Light silverballi. | 72. Wamara.             |
| 11. Crab wood.        | 32. Hyalya.                         | 52. Masarinnui.        | 73. Wadaduri.           |
| 12. Contaballi.       | 33. Iac kin.                        | 53. Murwana.           | 74. Wild orange.        |
| 13. Carahari.         | 34. Ilikinibumballi                 | 54. Mora               | 75. Washuba.            |
| 14. Cefire.           | 35. Kretti, or bastard silverballi. | 55. Purpleheart.       | 76. Wana coum.          |
| 15. Canaballi.        | 36. Kinaa                           | 56. Putti              | 77. Wallaba.            |
| 16. Cabacalli.        | 37. Kakanalli                       | 57. Red cedar.         | 78. Waruma.             |
| 17. Carbacalli.       | 38. Kataballi.                      | 58. Rosewood.          | 79. Yellow silverballi. |
| 18. Calabash.         | 39. Kammusick.                      | 59. Sand Mora.         | 80. Youraballi.         |
| 19. Cabbage tree.     | 40. Keria.                          | 60. Snowy              | 81. Yerara.             |
| 20. Canela.           | 41. Kakakasa.                       | 61. Simaruba           | 82. Yarri yarri.        |
| 21. Ducaluballi.      |                                     | 62. Sunadanni.         |                         |

## WOODS OF BAHAMA.

A fine series of the woods of Bahama is included in the collection of raw produce from that colony. The specimens contributed by Messrs. BAINES (p. 97b) were deemed worthy of Honourable Mention.

1. Cedar - - - - - Is used principally in house-building, for door and window frames, piazza-posts, sills, girders, &c. It grows on several of the Bahama Islands, but is found in greatest abundance on Andros Island; and its size, when full-grown, is from 16 to 20 feet in length, and 1 foot in diameter; it is generally cut 10 to 16 feet in length, and from 5 to 8 inches square: the branches are used for boats' timbers. This is one of the most durable of the Bahamian wood. A soft, fine, close-grained, rather light wood, possessing the pink hue, and emitting the fragrant odour of the common pencil cedar.
2. Cedar - - - - - This wood is used principally for picture-frames and other ornamented articles of cabinet-work; there is no difference between it and No. 1, except its curled and shaded appearance, which is said to be obtained by its growth in a very rocky soil.
3. Horseflesh mahogany - Is principally used in house-building, the branches and crooked trees for ships' timbers; it is a very durable wood, and grows on several of the Bahama Islands, but is found of large size, and in greater quantities at Andros Island, where it grows to about 20 feet in length, and 2 feet in diameter; it is, however, seldom brought out of the woods of that size, from the want of proper means of conveyance. A hard, fine-grained wood, heavy, and exhibiting numerous open cells.
4. Dogwood - - - - - The principal uses made of this wood are for felloes of wheels and ships' timbers; from its ugliness and other properties, it is better adapted to the former purpose than any other of the Bahamian woods. The tree does not attain any considerable size, and is generally crooked. A rather soft, open-grained, light, but evidently very tough wood.
5. Stopper wood - - - - - Used principally for piles to wharfs, and for wheel spokes; it is a very strong and durable wood; it grows from 12 to 16 feet long, and from 6 to 8 inches in diameter; it is found on all the Bahamian islands. An exceedingly hard, fine, close-grained, very heavy wood.
6. Lignum - - - - - This wood grows on several of the Bahama Islands, and is generally exported to Europe and America, where it is used for sheaves to blocks, &c. The principal use made of it in the Bahamas is for hinges and fastenings for houses situated by the sea-shore, or in the vicinity of salt-ponds on the out-islands, where, from the quick corrosion of iron, hinges, &c., of that metal are seldom used.
7. Bahama Satin wood - This wood, commonly called yellow wood, grows abundantly on Andros Island, and others of the Bahamian group; it grows to a large size. A hard, fine, close-grained wood, showing on its polished surface a beautifully rippled pattern.

## WOODS OF BAHAMA—continued.

8. Bahama Satin wood - - Specimen of a deeper colour, showing a pretty mottled pattern.
9. Bahama mahogany - - This wood, commonly called "Madeira," grows abundantly on Andros Island, and others of the Bahamas group, is not exceeded in durability by any of the Bahamas woods: it grows of a large size, but is generally cut of small dimensions, owing to the want of proper roads, and other means of conveyance; it is principally used for bedsteads, &c., and the crooked trees and branches for ships' timbers. A hard, fine, and rather close-grained, moderately heavy wood, of a fine rich colour, equal to that of Spanish mahogany, although probably too hard to be well adapted for the purposes to which this latter is usually applied.
10. Crab wood - - - - Mostly used for picture-frames, walking-sticks, and small ornamented cabinet-work; it seldom grows larger than from 3 to 4 inches in diameter. A rather hard, fine, close-grained, moderately heavy wood; heart-wood of a beautiful veined Vandyke-brown, its external edge bright black, alburnum of a pure white.

A small collection of the woods of South America is exhibited by — DEACON. The specimens are very small, and amount to 39 in number; they include the calabash, ramwood, ebony, mahogany, sanden, green heart, box, fustic, rosewood, Brazillette, and various palms, &c.

## WOODS OF TRINIDAD.

Some very beautiful specimens of ornamental and other woods are shown in the excellent collection of the raw produce of Trinidad, contributed by His Excellency Lord HARRIS, the Governor (see p. 71). They are as follows:—

1. *Achras balata*, L. (balata or valata). A timber extensively used and much esteemed; diameter from 2 to 6 feet.
2. *Achras* (zapotilla or zapodilla).
3. *Achras*, sp. (ucuma or mastic). A timber held in high estimation, as indeed are all the woods derived from the present family of trees. It varies in diameter from 2 to 4 feet.
4. *Acrocomia sclerocarpa* (gru gru). Yields beautiful veneers. A palm.
5. *Astrocaryum aculeatum* (gri gri). Also appertaining to the order "Palme," and affording excellent veneers for ornamental purposes.
6. *Brosimum guianense* (letter-wood). The tree which yields this beautiful wood never attains a large size; its recent layers are of a uniform yellowish-white colour. The heart-wood only is used.
7. *Bucida Buceras* (olivia) - A coarse-grained strong wood, principally employed for making shingles; its diameter ranges from 2 to 4 feet.
8. *Carya guianensis* (carapa). Bears a considerable resemblance to cedar, and is extensively used and much esteemed; diameter from 2 to 3 feet.
9. *Cordia* (lorata (West India cedar)). A very useful and ornamental timber, from 3 to 12 feet in diameter.
10. *Cocos nucifera* (cocoa-nut). The cocoa-nut palm.
11. *Copaifera officinalis* (copai). A beautiful and durable wood.
12. *Cordia*, sp. (sepe) - - A light wood, resembling English elm, impregnated with a bitter principle, which preserves it from the attack of insects: it is much valued; diameter from 1 to 2 feet.
13. *Crescentia Cujete* (calabash). A very strong tough wood; used in boat-building, and for various other purposes, where these qualities are required; is very abundant, and ranges in diameter from 1 to 2 feet.
14. *Dalbergia*, sp. (roble).
15. *Geoffroya incrimis* (l'angeline). A strong hard wood, extensively used for naves of wheels, &c.
16. Grey mangrove.
17. *Guaiacum officinale* (guaiacan). Bois lizard.
18. *Hematoxylon campechianum* (log-wood).
19. *Hymenaea courbaril* (courbaril). West India locust: an abundant and valuable timber; diameter 2 to 6 feet.
20. *Lecythis Idatimon* (agua-taño).
21. *Mimosa juliflora* (yoke savan). A very hard and useful wood.
22. *Morus tinctoria* (fustic, or bois d'orange).
23. *Paltiva*.
24. Purple-heart - - - An abundant and useful timber, 2 to 4 feet in diameter.
25. *Rhopala montana* (agua-tapana). A very durable and curious wood, susceptible of a fine polish, 18 inches to 3 feet in diameter.
26. *Sideroxylon* (sp. ?) (iron-wood, or bois gri).
27. *Swietenia mahogani* (mahogany).
28. *Tapana* - - - - A very strong and tough wood, esteemed for felloes of wheels.
29. *Tecoma poul* (green poul).
30. *Tecoma serratifolia* (grey poul). These trees, belonging to the natural order "Bignoniaceæ," furnish the hardest and most durable of woods; their timber takes a fine polish, and has a peculiar colour; they furnish the favourite timbers of the colony, are very abundant, 3 to 4 feet diameter, and proportionably lofty.
31. *Tecoma* sp. (black poul).
32. Yoke - - - - A handsome wood, resembling mahogany, usually 2 to 3 feet diameter.

A very fine large specimen of "cedrela wood," or West Indian cedar (*Cedrela odorata*), from Trinidad, is exhibited by T. Y. C. BURNETT; this was deemed worthy of Honourable Mention.

The collection of Australian and Van Diemen's Land

woods is extensive and very interesting, many of woods being new, and some of them of remarkable beauty.

Amongst the specimens from New South Wales, must be mentioned the samples of Briggale or Bricklow, pro-

bably a variety of *Acacia*, exhibited by J. G. BIDWELL (14, p. 989); and two small collections, contributed by Messrs. DAY (2, p. 989), and by W. FRANCIS: the latter being intended as samples of woods suitable for railway sleepers, and similar engineering purposes. Messrs. DAY's series consists of

- |                                   |                   |
|-----------------------------------|-------------------|
| 1. Black butt.                    | 5. Colonial ash.  |
| 2. Box.                           | 6. Iron bark.     |
| 3. Beef-oak ( <i>Casuarina</i> ). | 7. Myrtle, white. |
| 4. Cedar.                         | 8. Sycamore.      |

Mr. W. FRANCIS's collection and that of Messrs. DAY were deemed worthy of Honourable Mention. It contains:

- |   |   |
|---|---|
| 1. Australian box.                      | 7. Flooded gum ( <i>Eucalyptus</i> , sp.)   |
| 2. " turf-wood.                         | 8. Iron bark, grey.                         |
| 3. " mahogany                           | 9. " red                                    |
| ( <i>Eucalyptus</i> , sp.)              | 10. Swamp oak ( <i>Casuarina</i> , sp.)     |
| 4. Blue gum.                            | 11. Stringy bark ( <i>Eucalyptus</i> , sp.) |
| 5. Black butt.                          |   |
| 6. Forest-oak ( <i>Casuarina</i> , sp.) |   |

#### WOODS OF WESTERN AUSTRALIA.

In the interesting and valuable collection of the Colonization Assurance Company, already alluded to (see p. 8), are some fine specimens of the woods of the country, including some remarkable pieces of *Eucalyptus* wood. It is however stated, that owing to the period of the year when they were collected, the short time which could be devoted to their preparation, and the want of proper saws, &c., the specimens sent are not to be considered as fairly representing the woods of this part of the country. The woods sent are,—

1. Banksia, sp. — — — Abundant throughout the colony; a very ornamental wood; the specimen sent is from Guildford.
2. Cypress — — — Abundant on Garden Island, Rottnest, and also in some places on the mainland.
3. Jam-wood — — — A species of *Acacia*, commonly called "raspberry-jam wood," in consequence of its peculiar odour, resembling raspberries. It grows abundantly throughout the settled districts; it is well adapted for turning, and as it takes a very high polish, is suitable for all sorts of cabinet-work.
4. Jarrah (*Eucalyptus*, sp.) This excellent wood, considered to be admirably adapted for ship-building, and indeed for all other purposes, as it withstands the attacks of the white ant and the teredo, &c., can be obtained in any quantity; it may be had in planks, 8 feet wide. The plank exhibited was cut by W. P. Clifton, and is more than 4 feet wide.
5. Morrell (*Eucalyptus*, sp.) Said to be a most excellent wood, both for cabinet work and for treemills. It is abundant in some parts, about 60 miles from the sea-shore; grows to a great height, and attains a diameter of more than 3 feet. For the manufacture of spokes and other wheelwrights' work it is excellent.
6. Red ebony (?) — — — Said to be very abundant at Sharks' Bay, and along the sea-coast; this wood is very different from the red ebony exhibited from Port Natal.
7. Red gum (*Eucalyptus resinifera*). The tree is very abundant throughout the colony, and the wood is admirably adapted for wheelwrights' work.
8. Salmon bark (*Eucalyptus* sp.) A good durable wood, much used for farming implements. It is tolerably abundant in York district, and grows to a considerable size.
9. Sandal-wood — — — Abundant in the settled districts beyond the Darling range, at a distance of about 50 miles from the sea-coast. It has lately been discovered, of a very superior quality, on the coast at Sharks' Bay.
10. Satin-wood — — — Occurs in the island of Rottnest.
11. She-oak (*Casuarina*) — Very abundant.
12. Tuart (*Eucalyptus*, sp.) A noble timber; tolerably abundant on the coast, and said to be well adapted for ship-building and general purposes. The plank exhibited is more than 3 feet wide, and is contributed by W. P. Clifton, of Bunbury. Planks, some 10 feet wide, may be obtained.
13. York gum (*Eucalyptus*, sp.) Excrecences formed on the stem of this and also of some other *Eucalypti*, similar to the "Kaya boku" of the Lingao wood, and like it, well adapted for fancy cabinet-work. It is stated that the exhibitors had hoped to have procured and sent a plank of the Blue gum (*Eucalyptus globulus*) from the Deep river, 14 feet in width, but were unable to do so, for want of saws of sufficient size.

A very remarkable and interesting collection of the woods of Van Diemen's Land, is formed by the contributions of His Excellency Sir W. T. DENISON, Messrs. FOWLER, WHITESIDES, McNAUGHTEN, HADDEN, BROWNIDGE, and HOOD. To each of these the Jury severally awarded a Prize Medal. The specimens shown are as follows:—

BROWNIDGE.—Musk-wood (107, 108, p. 991).

Sir W. T. DENISON.—Blue gum, stringy bark, black wood, sassafras, myrtle, musk-wood, cedar, celery-pine, rose-wood, dog-wood, Norfolk Island pine, white oak, iron-wood, and maple (1, p. 992).

FOWLER, of Maria Island.—Dog-wood, musk-wood, he-oak, and Tasmanian iron-wood (82-89, p. 994).

Capt. W. C. HADDEN.—Musk-wood (103, 104, p. 991).

R. V. HOOD.—Silver wattle, musk-wood, black-wood,

Huon pine, and myrtle (111-120, p. 994).

McNAUGHTEN, of Hobart Town.—Musk-wood (209, p. 996).

J. WILLIAMS.—Richea-wood, pink-wood, and Oyster-bay pine (341, 342, p. 999).

WHITESIDES, of Hobart Town. Black-wood, myrtle-wood, and musk wood (91-93, p. 994).

A remarkably large section of iron-wood is exhibited by EUSTON and MILLIGAN (108, p. 994); specimens of the Tolosa tree, honeysuckle, and she-oak, by H. HULL (208, p. 996); of oak, myrtle, cherry, and honeysuckle, by the Rev. E. FRILLMAN, of Brown's River (210, p. 994); of blue gum and maple by — QUIN, of Hobart Town (91, 95, p. 994); and of Norfolk Island pine, by Lieut. ALKEN, R.E. (328, p. 998). Each of these was deemed worthy of Honourable Mention.

These various woods are arranged in the following table. One of the most remarkable of the specimens shown is the blue gum exhibited by Sir W. DENISON; it consists of two pieces, one a section of the tree just above the surface of the ground, and about 6 feet in diameter; the second a section of the same tree, 184 feet from the preceding one, and which measures about 24 feet across.

#### WOODS OF VAN DIEMEN'S LAND.

Black-wood (*Acacia melanoxylon*).

A very hard, close-grained, dark, and richly-colored wood; well adapted for cabinet-work of all sorts, and may be had in any quantity, and of large size. The beauty of this fine wood is admirably shown in some of the articles of furniture exhibited, in which its dark hue is well contrasted with the equally beautiful light wood of the Huon pine.

WOODS OF VAN DIEMEN'S LAND—*continued*.

2. Blue gum (*Eucalyptus globulus*). An enormous tree; it is said to be equal to oak for ship-building, and may be obtained in beams of any dimension up to 200 feet in length. It appears somewhat premature to speak very decidedly of the value of this comparatively new wood, but, from the practical results already obtained, it certainly promises to be a most important material for the ship-builder. A blue gum tree near Tobosa, on the northern aspect of Mount Wellington range, measured upwards of 30 feet in diameter at the base; and this is by no means unusually large for the trees of this species. According to the Rev. Mr. Ewing, a swamp gum-tree has been measured 10½ feet in circumference, at 3 feet from the ground.
3. Cedar, or Pencil pine (*Arthrotaxis selaginoides*?). It grows in the mountain ravines and gorges, and in the high table-land about 4000 feet above the level of the sea.
4. Celery pine (*Phyllocladus asplenifolia*). A handsome tree, which grows in the cold and moist parts of Van Diemen's Land, and attains a height of 150 feet. The wood is close-grained, and beautifully white; it is well adapted for household purposes.
5. Cherry (*Exocarpus cupressiformis*). A small graceful tree with lively green foliage: thinly scattered on the eastern side of the colony. It is useful as a cabinet wood, and forms good ornamental veneers.
6. Dog-wood (*Bedfordia*, sp.) This tree attains to considerable size in Maria Island; the wood is very richly and beautifully marked, it is consequently an excellent cabinet wood, and well adapted for all sorts of ornamental work.
7. Honeysuckle (*Banksia australis*). A low shrubby tree; the wood is handsome, and useful for cabinet work and for veneering. The bark is employed in tanning.
8. Moon Pine (*Dactyidium Franklinii*). A most remarkably beautiful light-coloured wood, singularly marked with dark spots, especially towards the lower part of the stem: admirable for ornamental furniture.
9. Pe-oak (*Casuarina stricta*). A low tree, of no great beauty or value, which grows upon the open grounds.
10. Iron-wood (*Notilia lignstrina*). A tree which rarely attains a greater diameter than 12 to 14 inches; the specimen exhibited, however, is nearly 2 feet. The wood is very hard and dense, and has been consequently made into sheaves for ships' blocks.
11. Iron-wood of Norfolk Island (*Olea apetala*). Said to be the most durable of all the Norfolk Island woods.
12. Maple of Norfolk Island.
13. Musk-wood (*Eurybia argophylla*). A comparatively small tree, which grows only in dense forests and close, damp situations. The wood is close-grained, very beautifully marked, especially at the lower part of the butt, and takes a fine polish. It is most admirably adapted for veneering and other cabinet-work.
14. Myrtle (*Fagus Cunninghamii*). This tree forms dense forests in parts which extend for many miles; the tree sometimes attains a girth of 30, or even 40 feet, and a proportionate height. The wood is hard, very close-grained, and has a fresh pink or red colour. The lower part of the stem is often very beautifully veined, rendering it excellent for cabinet-work; it takes a beautiful polish.
15. Pine, Oyster-bay (*Callitris australis*). Grows only on the eastern coast. The wood is used for internal fittings in houses, and for agricultural implements.
16. Pine, Norfolk Island (*Artocarpus excelsa*). Very transparent in the pieces—a good wood for turning.
- Pink-wood (*Carpodanthus lucida*). Grows chiefly on the western side of the island, in the dense myrtle forests. It attains a height of 100 to 150 feet, with a clean straight stem. The wood is fine-grained, and very hard; it has been used for the sheaves of ship blocks.
18. Richea-wood (*Richea pandanifolia*). Grows only in the dense moist forests on the western side of the island; attains a height of 30 or 40 feet, and a diameter of 10 inches.
19. Rose-wood, or Zebra-wood (*Acacia*, sp.) Said to be plentiful in Lake country, and about Mailborough.
20. Sasaparilla-wood (*Atherospora moschatum*). A moderate-sized tree; very abundant. The wood is soft, even, and close-grained; well adapted for internal building, flooring-boards, cabin-fittings, &c.; it turns well.
21. She-oak, or Reef-wood (*Casuarina quadrivalvis*). A hard and beautifully-marked cabinet-wood; it takes a high polish.
22. Silver wattle (*Acacia dealbata*).
23. Stringy-bark (*Eucalyptus robusta*). An enormous tree; very abundant. A stringy bark tree, near the Cam river, on the north-west coast, measures 200 feet to the first limb, and has been calculated to contain in the trunk alone 22½ tons of timber. The wood is rather coarser than that of the blue gum, and is chiefly used for house and ship-building, and for fencing; it is especially esteemed for treenails.
24. White-wood (*Pittosporum bicolor*). Seldom acquires a greater diameter than a foot. The wood has a remarkably close even grain, and might therefore, perhaps, be employed by wood-engravers. It is used by the natives for their "wuddies," or war-tubs.
25. White Oak of Norfolk Island (*Hibiscus Patersonii*).

A valuable little collection of the woods of New Zealand is contributed by Tao Nui, a native chief (44). For these the Jury awarded a Prize Medal.

Two small collections of the woods of New Zealand are exhibited by J. JOHNSON (21, p. 1001), and by W. FOX. These were deemed worthy of Honourable Mention.

## WOODS OF AMERICA.

The collection of American woods is by no means numerous. It consists of two separate series, and a few isolated specimens; the series contributed by R. J. PELL, of New York (115, p. 1440), consists of 167 specimens; unfortunately, however, many of these are cut from small branches or young trees, and do not therefore well show the characters of the wood; it was, nevertheless, deemed worthy of Honourable Mention.

|---------------------------------|------------------|-------------------------------|--------------------|
| 1. <i>Acer striatum</i> - - -   | Moose wood.      | 8. <i>Betula populifolia</i>  | White birch.       |
| 2. <i>Acer</i> - - - - -        | Bird's-eye maple | 9. <i>Cupressus juniperus</i> | Cypress cedar.     |
| 3. <i>Abies canadensis</i> - -  | Hemlock spruce.  | 10. <i>Castanea vesca</i>     | American chestnut. |
| 4. <i>Acer eriocarpum</i> - - - | White maple.     | 11. <i>Cerasus virginiana</i> | Wild cherry.       |
| 5. <i>Acer saccharinum</i> - -  | Sugar maple.     | 12. <i>Carya tomentosa</i> -  | Common hickory.    |
| 6. Boxwood.                     |                  | 13. <i>Myopyros</i> - - -     | Persimon           |
| 7. Blue dogwood.                |                  |                               |                    |

## WOODS OF AMERICA—continued.

|                                       |                     |                                      |                    |
|---------------------------------------|---------------------|--------------------------------------|--------------------|
| 14. <i>Fagus ferruginea</i> - - -     | Red beech.          | 61. <i>Taxus rubra</i> - - -         | Red larch.         |
| 15. <i>Gleditsia triacanthus</i> - -  | Sweet locust        | 62. <i>Liquidambar styraciflua</i> - | Gum tree.          |
| 16. <i>Horseshoe-wood</i> - - -       |                     | 63. <i>Liriodendron tulipifera</i> - | Tulip tree.        |
| 17. <i>Ilex opaca</i> - - -           | Holly.              | 64. <i>Morus alba</i> - - -          | White mulberry.    |
| 18. <i>Juniperus sabinx</i> - - -     | Cedar.              | 65. <i>Morus nigra</i> - - -         | Black mulberry.    |
| 19. <i>Juglans nigra</i> - - -        | Black walnut.       | 66. <i>Morus rubra</i> - - -         | Red mulberry.      |
| 20. <i>Juglans squamosa</i> - - -     | Shell-bark hickory. | 67. <i>Morus</i> - - -               | Mulberry.          |
| 21. <i>Juniperus virginiana</i> - -   | Red cedar.          | 68. <i>Maclura aurantiaca</i> - -    | Osage orange.      |
| 22. <i>Laurus sassafras</i> - - -     | Sassafras.          | 69. <i>Magnolia glauca</i> - - -     |                    |
| 23. <i>Liquidambar styraciflua</i> -  | Gum tree.           | 70. <i>Magnolia grandiflora</i> -    |                    |
| 24. <i>Liriodendron tulipifera</i> -  | Tulip tree.         | 71. <i>Magnolia acuminata</i> - -    | Cucumber magnolia. |
| 25. <i>Ornus rotundifolia</i> - - -   | Manna ash.          | 72. <i>Malus</i> - - -               | Apple.             |
| 26. <i>Pinus mitis</i> - - -          | Yellow pine.        | 73. <i>Nyssa biflora</i> - - -       | Pepperidge.        |
| 27. <i>Pinus Stroblis</i> - - -       |                     | 74. <i>Nyssa capitata</i> - - -      | Sour tupelo.       |
| 28. <i>Pinus rubra</i> - - -          | Red pine.           | 75. <i>Ornus rotundifolia</i> - - -  | Manna ash.         |
| 29. <i>Platanus occidentalis</i> - -  | Plane tree.         | 76. <i>Punica granatum</i> - - -     | Pomegranate.       |
| 30. <i>Quercus palustris</i> - - -    | Pine oak.           | 77. <i>Populus argentea</i> - - -    | Cotton tree.       |
| 31. <i>Quercus alba</i> - - -         | White oak.          | 78. <i>Populus tremuloides</i> - -   | Aspen poplar.      |
| 32. <i>Quercus Prinos monticola</i> - | Rock chestnut oak.  | 79. <i>Populus angulata</i> - - -    | Common poplar.     |
| 33. <i>Quercus Prinos acuminata</i> - | Yellow oak.         | 80. <i>Populus alba</i> - - -        | White poplar.      |
| 34. <i>Quercus virens</i> - - -       | Live oak.           | 81. <i>Populus balsamifera</i> - -   | Balsam poplar.     |
| 35. <i>Swietenia</i> - - -            |                     | 82. <i>Platanus occidentalis</i> -   | Plane tree.        |
| 36. <i>Thuja occidentalis</i> - - -   | White cedar.        | 83. <i>Pearmain apple</i> - - -      |                    |
| 37. <i>Tilia americana</i> - - -      | Bass wood.          | 84. <i>Pinus mitis</i> - - -         | Yellow pine.       |
| 38. <i>Ulmus rubra</i> - - -          | Red elm.            | 85. <i>Pinus Strobus</i> - - -       | White pine.        |

## SPECIMENS IN BARK.

|                                       |                         |  |                    |
|---------------------------------------|-------------------------|--|--------------------|
| 1. <i>Ailanthus</i> - - -             |                         | 86. <i>Pinus ruspestus</i> - - -       | Grey pine.         |
| 2. <i>Acer saccharinum</i> - - -      | Sugar maple.            | 87. <i>Pinus australis</i> - - -       | Long-leaved pine.  |
| 3. <i>Acer rubrum</i> - - -           | Scarlet maple.          | 88. <i>Prunus americana</i> - - -      | Wild plum.         |
| 4. <i>Alnus serrulata</i> - - -       | Common alder.           | 89. <i>Prunus domestica</i> - - -      | Plum.              |
| 5. <i>Acer Negundo</i> - - -          | Box elder.              | 90. <i>Prunus Armeniaca</i> - - -      | Apricot.           |
| 6. <i>Amygdalus Persica</i> - - -     | Peach.                  | 91. <i>Prunus cerasus</i> - - -        | Cherry plum.       |
| 7. <i>Acer grandidentatum</i> - -     | Mountain maple.         | 92. <i>Pyrus aviculans</i> - - -       | Crab apple.        |
| 8. <i>Acer rubrum</i> - - -           | Scarlet maple.          | 93. <i>Pyrus communis</i> - - -        | Pear.              |
| 9. <i>Aesculus rubicunda</i> - -      | Red flowering chestnut. | 94. <i>Pyrus Cydonia</i> - - -         | Quince.            |
| 10. <i>Alnus serrulata</i> - - -      | Hazel-leaved alder.     | 95. <i>Philadelphus syringa</i> -      | Lilac.             |
| 11. <i>Abies</i> - - -                | Hemlock.                | 96. <i>Quercus ferruginea</i> - - -    | Black oak.         |
| 12. <i>Acer eriocarpum</i> - - -      | White maple.            | 97. <i>Quercus Prinos monticola</i> -  | Rock-chestnut oak. |
| 13. <i>Alnus glauca</i> - - -         | Black alder.            | 98. <i>Quercus oliviformis</i> - -     | Mossy-cup oak.     |
| 14. <i>Abies nigra</i> - - -          | Black spruce.           | 99. <i>Quercus Phellos</i> - - -       | Willow oak.        |
| 15. <i>Acacia</i> - - -               |                         | 100. <i>Quercus Prinos acuminata</i> - | Yellow oak.        |
| 16. <i>Betula lenta</i> - - -         | Black birch.            | 101. <i>Quercus Prinos discolor</i> -  | Swamp white pine.  |
| 17. <i>Betula papyracea</i> - - -     | Canoe birch.            | 102. <i>Quercus palustris</i> - - -    | Pine oak.          |
| 18. <i>Betula rubra</i> - - -         | Red birch.              | 103. <i>Quercus rubra</i> - - -        | Red oak.           |
| 19. <i>Betula populifolia</i> - - -   | White birch.            | 104. <i>Quercus Phellos</i> - - -      | Willow oak.        |
| 20. <i>Blue dogwood</i> - - -         |                         | 105. <i>Quercus ambigua</i> - - -      | Grey oak.          |
| 21. <i>Carya microcarpa</i> - - -     | Nutmeg hickory.         | 106. <i>Quercus Bamsteri</i> - - -     | Boon oak.          |
| 22. <i>Castanea vesca</i> - - -       | American chestnut.      | 107. <i>Quercus alba</i> - - -         | White oak.         |
| 23. <i>Cerasus virginiana</i> - - -   | Wild cherry.            | 108. <i>Quercus heterophylla</i> -     | Bartram oak.       |
| 24. <i>Cornus alba</i> - - -          | White dogwood.          | 109. <i>Rhus</i> - - -                 | Sumach.            |
| 25. <i>Carya pecan</i> - - -          | Pecan-nut hickory.      | 110. <i>Rhamnus maritima</i> - -       | Buckthorn.         |
| 26. <i>Carya porcina</i> - - -        | Bitter-nut hickory.     | 111. <i>Rhus rubra</i> - - -           | Red sumach.        |
| 27. <i>Carpinus</i> - - -             | Hornbeam.               | 112. <i>Robinia Pseudacacia</i> -      | Yellow locust.     |
| 28. <i>Castanea alnifolia</i> - - -   | Dwarf chestnut.         | 113. <i>Salix alba</i> - - -           | White willow.      |
| 29. <i>Corylus avellana</i> - - -     | Hazle.                  | 114. <i>Salix lucida</i> - - -         | Shining willow.    |
| 30. <i>Carya pecan</i> - - -          | Pecan-nut hickory.      | 115. <i>Salix lutea</i> - - -          | Yellow willow.     |
| 31. <i>Crataegus coccinea</i> - - -   | Scarlet thorn.          | 116. <i>Salix triandra</i> - - -       | Basket willow.     |
| 32. <i>Castanea alnifolia</i> - - -   | Red flowering chestnut. | 117. <i>Salix nigra</i> - - -          | Black willow.      |
| 33. <i>Crataegus populifolia</i> - -  | Washington thorn.       | 118. <i>Sorbus Aucuparia</i> - - -     | Mountain ash.      |
| 34. <i>Carya microcarpa</i> - - -     | Small-fruited hickory.  | 119. <i>Salix vitellina</i> - - -      | Common willow.     |
| 35. <i>Campinus Ontyra</i> - - -      | Iron wood.              | 120. <i>Summer queen apple</i> -       |                    |
| 36. <i>Carya porcina</i> - - -        | Pig-nut hickory.        | 121. <i>Silver aberle</i> - - -        |                    |
| 37. <i>Cytisus</i> - - -              | Laburnum.               | 122. <i>Spitzenburgh apple</i> -       |                    |
| 38. <i>Cerasus borealis</i> - - -     | Red cherry.             | 123. <i>Sambucus</i> - - -             | Elder.             |
| 39. <i>Carya amara</i> - - -          | Butter-nut hickory.     | 124. <i>Thuja alba</i> - - -           | White lime tree.   |
| 40. <i>Carpinus</i> - - -             | Hornbeam.               | 125. <i>Thuja occidentalis</i> - -     | White cedar.       |
| 41. <i>Celtis crassifolia</i> - - -   | Hackberry.              | 126. <i>Ulmus rubra</i> - - -          | Red elm.           |
| 42. <i>Cereis</i> - - -               | Judas tree.             | 127. <i>Ulmus alba</i> - - -           | White elm.         |
| 43. <i>Fraxinus</i> - - -             | White ash.              | 128. <i>Vitis vinifera</i> - - -       | Grape vine.        |
| 44. <i>Fraxinus sambucifolia</i> - -  | Black ash.              | 129. <i>Viburnum</i> - - -             |                    |
| 45. <i>Fagus ferruginea</i> - - -     | Red beech.              |  |                    |
| 46. <i>Fraxinus</i> - - -             | Common ash.             |  |                    |
| 47. <i>Fagus sylvestris</i> - - -     | White beech.            |  |                    |
| 48. <i>Fraxinus viridis</i> - - -     | Green ash.              |  |                    |
| 49. <i>Fraxinus acuminata</i> - - -   | Witch elm.              |  |                    |
| 50. <i>Fraxinus</i> - - -             | White ash.              |  |                    |
| 51. <i>Hibiscus syriacus</i> - - -    | Althaea frutex.         |  |                    |
| 52. <i>Imperialis</i> - - -           |                         |  |                    |
| 53. <i>Juniperus occidentalis</i> - - | Juniper.                |  |                    |
| 54. <i>Juniperus rubra</i> - - -      | Red cedar.              |  |                    |
| 55. <i>Juglans ascania</i> - - -      | Butter nut.             |  |                    |
| 56. <i>Juglans</i> - - -              | Black walnut.           |  |                    |
| 57. <i>Laurus benzoin</i> - - -       | Spice-wood.             |  |                    |
| 58. <i>Laurus sassafras</i> - - -     | Sassafras.              |  |                    |
| 59. <i>Lady apple</i> - - -           |                         |  |                    |
| 60. <i>Larix americana</i> - - -      | Black larch.            |  |                    |

## WOODS OF VERMONT.

|                                  |                     |
|----------------------------------|---------------------|
| 1. <i>Acer rubrum</i> - - -      | Red maple.          |
| 2. <i>Acer saccharinum</i> - - - |                     |
| 3. <i>Betula excelsa</i> - - -   | birch.              |
| 4. <i>Carya squamosa</i> - - -   | Shell-bark hickory. |
| 5. <i>Cerasus serotina</i> - - - | Black cherry.       |
| 6. <i>Fagus ferruginea</i> - - - | Red beech.          |

The second collection, that exhibited by the Rev. Z. Thompson, of Burlington (241, p. 1451), consists of better-selected specimens of the woods of Vermont, and is accompanied by a good series of descriptive labels, reprinted from his own useful work on the "Natural History of Vermont," conveying a good deal of valuable local as well as scientific information: for this collection the Jury awarded a Prize Medal.

## WOODS OF AMERICA—continued.

|                                      |                              |
|--------------------------------------|------------------------------|
| 7. <i>Fraxinus acuminata</i> - -     | White ash.                   |
| 8. <i>Fraxinus pubescens</i> - -     | Red ash.                     |
| 9. <i>Fraxinus sambucifolia</i> - -  | Black ash.                   |
| 10. <i>Juglans cinerea</i> - -       | Butter-nut.                  |
| 11. <i>Juniperus virginiana</i> - -  | Red cedar.                   |
| 12. <i>Ostrya virginica</i> - -      | Iron-wood.                   |
| 13. <i>Pinus balsamea</i> - -        | Silver or balsam fir.        |
| 14. <i>Pinus canadensis</i> - -      | Hemlock.                     |
| 15. <i>Pinus nigra</i> - -           | Double spruce.               |
| 16. <i>Pinus resinosa</i> - -        | Norway pine.                 |
| 17. <i>Pinus strobus</i> - -         | White pine.                  |
| 18. <i>Platanus occidentalis</i> - - | Button wood, or sycamore.    |
| 19. <i>Robinia pseudacacia</i> - -   | Locust wood.                 |
| 20. <i>Thuja occidentalis</i> - -    | White cedar, or arbor vitae. |
| 21. <i>Tilia americana</i> - -       | Bass-wood, or lime-tree.     |
| 22. <i>Ulmus americana</i> - -       | White elm.                   |
| 23. <i>Ulmus fulva</i> - -           | Red or slippery elm.         |

|   |                     |
|---|---------------------|
| 1. <i>Acer eriocarpum</i> - -           | White maple.        |
| 2. <i>Acer saccharinum</i> - -          | Sugar maple.        |
| 3. <i>Carya tomentosa</i> - -           | Common hickory.     |
| 4. <i>Diospyros</i> , sp. - -           | Persimmon.          |
| 5. <i>Fagus ferruginea</i> - -          | Red beech.          |
| 6. <i>Gleditsia triacanthos</i> - -     | Sweet locust.       |
| 7. <i>Horse-flesh</i> - -               |                     |
| 8. <i>Ilex opaca</i> - -                |                     |
| 9. <i>Juglans nigra</i> - -             | Black walnut.       |
| 10. <i>Juniperus Sabina</i> - -         | Cedar.              |
| 11. <i>Juniperus virginiana</i> - -     | Red cedar.          |
| 12. <i>Pinus strobus</i> - -            | White pine.         |
| 13. <i>Quercus alba</i> - -             | White oak.          |
| 14. <i>Quercus Prinos acuminata</i> - - | Yellow oak.         |
| 15. <i>Quercus Prinos monticola</i> - - | Black chestnut oak. |
| 16. <i>Quercus villosa</i> - -          | Laye oak.           |

A sample of sweet gum-wood is contributed by J. B. DE LAUSURE, of Charleston (176A. p. 148).

A few good specimens of the chief woods of Maryland are also exhibited by the MARYLAND COMMISSIONERS (371, p. 1459), consisting of ash, beech, cedar, cherry, hickory, holly, locust, maple, mulberry, oak, pine, poplar, and walnut; these were deemed worthy of Honourable Mention. (See p. 71.)

Specimens of Palmetto cedar, live oak, and a few other woods, are exhibited by E. B. BELL, of Charleston, South Carolina (176, p. 1448); these also were deemed worthy of Honourable Mention. It is hardly necessary to advert to the importance of the wood of the live oak, *Quercus rubra*, its value as a ship timber being universally known and recognised.

The only specimens of wood exhibited in the Austrian Collection are a series of pine planks, *Abies taifolia*, as prepared for the uses of musical-instrument makers, chiefly for sounding-boards, shown by D. BRENNER and SONS, of Maderhausen (143, p. 1015.) The wood of this tree is remarkably homogeneous, and when fairly grown, is peculiarly free from knots, or irregularities of any kind; it possesses in an eminent degree those qualities which are essential for sounding-boards. A section of a tree more than 3 feet in diameter is shown, in which upwards of 170 concentric rings, or circles, can be counted; from this it is presumed that the tree must have been nearly five centuries old. These specimens were deemed worthy of Honourable Mention.

## WOODS OF CHINA

A numerous collection of the woods of China is exhibited by the Rev. Dr. PARKER (12, p. 1422). It is much to be regretted that these specimens are so small as scarcely to show the characters of the woods; many of the specimens have no labels, and of those which have, a considerable number are evidently incorrectly named; the following is a list of the labels:—

|                        |                                |  |
|------------------------|--------------------------------|--|
| 1. Canton rosewood.    |                                |  |
| 2. Chan muh - -        | Pine-wood.                     |  |
| 3. Chang muh - -       | Camphor-wood.                  |  |
| 4. Chau muh - -        |                                |  |
| 5. Chung fu - -        |                                | An inferior kind of pine.                              |
| 6. Ebony.              |                                |  |
| 7. Hwang jung muh      | Yellow Dryandra.               |  |
| 8. " muh - -           | Yellow-wood.                   |  |
| 9. Hwa Nien - -        | Averrhoa Carambola.            |  |
| 10. Ize King muh - -   | Thorn-wood.                    |  |
| 11. Kan muh - -        |                                | Wood of the Coolie orange                              |
| 12. Kau muh.           |                                | A fine wood for cabinet-work.                          |
| 13. Kuin tien kuh - -  |                                |  |
| 14. Kih now muh.       |                                |  |
| 15. Kung muh - -       | Tallow tree (?)                |  |
| 16. Kwang lang - -     | Dryandra, sp. - - -            | Used for rhills of sedans.                             |
| 17. Lew muh - -        | Willow.                        |  |
| 18. Iung yen muh - -   | Dimocarpus juncea.             |  |
| 19. Lan muh - -        | Canarium Pimela - -            | Wood of the Chinese olive                              |
| 20. Ma me muh - -      |                                | A resinous pine.                                       |
| 21. Mango-trer wood.   |                                |  |
| 22. Mai muh - -        | Apricot-wood.                  |  |
| 23. Muh mien - -       | Bouffax Ceiba - - -            | Wood of the cotton-wood tree.                          |
| 24. Nan-chi-muh - -    |                                | A fine wood from Cochinchina.                          |
| 25. Oil-wood.          |                                |  |
| 26. Pah-muh - -        | Cedar (?) - -                  |  |
| 27. Plum-wood - -      |                                | Used for cutting blocks for books.<br>(rather coarse.) |
| 28. Pride of India - - | Melia Azaderachta.             |  |
| 29. Red-wood.          |                                |  |
| 30. Rose-wood - -      |                                | From Siam.   |
| 31. Sandal-wood.       |                                |  |
| 32. Sang muh - -       | Mulberry.                      |  |
| 33. Sata-wood.         |                                |  |
| 34. Shan che - -       | Wild tea - - -                 | A lofty tree   |
| 35. " che.             |                                |  |
| 36. " muh - -          | Pride of India.                |  |
| 37. Sha tea shah - -   |                                | A kind of willow.                                      |
| 38. Shui sha muh - -   |                                | Used for coffins.                                      |
| 39. Siang la muh - -   | Maple.                         |  |
| 40. Sung muh - -       | Fir.                           |  |
| 41. Tan liang muh - -  | Sandal-wood.                   |  |
| 42. Tan kwa san - -    | Peach flower. Pride of India - | Called "China mahogany," at Canton.                    |

## WOODS OF CHINA—continued.

|                    |                             |                                    |
|--------------------|-----------------------------|------------------------------------|
| 43. Tsung muh —    | Fir —                       | Used for fuel and boxes.           |
| 44. Tu muh —       | Pine —                      | Used for furniture                 |
| 45. Varnish-wood — | Cinnamum alba.              |                                    |
| 46. Wuo tung —     | Dryandra cordifolia —       | Wood used for musical instruments. |
| 47. Wu tung muh —  |                             |                                    |
| 48. Ying muh —     | Knot-wood, or Amboyna-wood. |                                    |
| 49. Ying —         |                             | Sapwood of a kind of beech.        |
| 50. Yung muh —     |                             | Wood of the bastard banian.        |

## WOODS OF EGYPT.

Fine specimens of the chief woods of Egypt are shown in the collection of Egyptian raw produce; the specimens are very good, and their interest is still further increased by their being accompanied by some of the agricultural and other implements made from them. The "Bois de Nabh," a hard, dark-coloured wood, resembling ebony, appears likely to be useful. The Acacia wood also seems to be a useful durable wood. The woods shown are:—

|                  |                                 |                     |                    |
|------------------|---------------------------------|---------------------|--------------------|
| 1. Acacia.       | 4. Date.                        | 6. Ebony of Sennar. | 8. Sycamore. Ficus |
| 2. Alizier wood. | 5. Dum palm. Cucifera Thebaica. | 7. Sweet palm.      | Sycamorus.         |
| 3. Azaderak.     |                                 |                     |                    |

## WOODS OF ALGERIA.

A highly-valuable collection of the woods of Algeria is shown in the Algerian Department of the French Collections. These specimens are remarkable for their beauty, and for the skilful and instructive manner in which they are exhibited. Some of them are rather small, but in all cases they are characteristic and well selected. Some of the woods are comparatively new to this country. They are as follows:—

|   |  |   |
|---|--|---|
| 1. Thuya-articulata; an evergreen tree                                  | Thuja articulata, Desf. ? 6 × 5 × 2              | Closely grain, hard, heart-wood (duramen) bright chestnut-coloured, resinous; recent layers (alburnum) cream-yellow. This wood is supposed by some to be the "sandal-wood" of the ancients. |
| 2. Pin pinier, an evergreen tree  | Pinus Pinet, 6 × 2½ × 1½                         | Specimen from a young tree, in bark; a resinous wood.   |
| 3. Grand cypres d'Italie; an evergreen tree.                            | Cupressus, sp. (?) 6 × 3½ × 2½                   | in bark; a resinous wood.   |
| 4. Ricin; a deciduous tree  | Paliurus, (?) 6 × 4 × 2½                         | an exceedingly soft, light, weak wood; in bark. (Palma Christi, or Christ's thorn).   |
| 5. Jujubier sativ —   | Ziziphus, sp. 6 × 5 × 2                          | An exceedingly close, fine-grained wood, heavy; heart bright-red chestnut, recent layers, pale ochreous; in bark.   |
| 6. Aune; a deciduous tree   | Alnus, 6 × 4 × 2                                 | a light, though fine, and close-grained, soft weak wood, of an uniform reddish-yellow throughout; in bark.  |
| 7. Pin maritime; an evergreen tree                                      | Pinus maritima, (?) 6 × 8 × 2                    | in bark; a resinous wood.   |
| 8. Saule fragile; a deciduous tree                                      | Salix fragilis, (?) 6 × 1½ × 1½                  | in bark; a soft and weak wood.  |
| 9. Gênerier Phénicien —   | Juniperus Phœnicea, (?) 6 × 5 × 2                | This specimen was cut from a portion of a tree having a diameter of about 9 inches only; in bark; from Zeralda.   |
| 10. Grand cypres —  | Cupressus, sp. 9½ × 4 × 2                        | from a tree 1 metre in diameter; from the environs of Blidah.   |
| 11. Sumac Thérèse —   | Ilex, sp., 9½ × 4 × 2                            | Wood heavy; its longitudinal section exhibits numerous open cells; in bark.   |
| 12. Jujubier des lotophages; a deciduous tree.                          | Ziziphus, sp., 6 × 1 × 1                         | in bark; a hard wood.   |
| 13. Phillyrea; a deciduous tree   | Phillyrea, sp., 6 × 5½ × 2                       | A close-grained, hard, and heavy wood.  |
| 14. Lentisque commun —  | Pistacia, sp., 8 × 5 × 2½                        | a hard, heavy wood.   |
| 15. Chêne-zeen —  | — 8 × 5½ × 2                                     | a tree, a metre in diameter, from Edough.   |
| 16. Grand bruyère arborescente, evergreen tree.                         | — 6½ × 2 × 2                                     | Wood fine, close-grained, hard. (Tree-like heath.)  |
| 17. Cèdre; an evergreen tree  | Cupressus, sp., 6 × 6 × 2                        | in bark; resinous wood.   |
| 18. Figuier sauvage, bois tendre à feuilles caduques; a deciduous tree. | Ficus Carica, 6 × 6 × 2                          | a soft and weak wood.   |
| 19. Pistachier-térébinthe; a deciduous tree.                            | Pistacia terebinthus, 8 × 6½ × 2                 | Wood close-grained, hard, heavy, and resinous.  |
| 20. Cythse —  | Cytisus, sp., 9 × 2½ × 1½                        | Wood fine and close-grained, hard, heavy; heart chestnut; recent layers narrowly white.   |
| 21. Tamaris; evergreen tree   | Tamarix, 6 × 6½ × 2½                             | in bark; a resinous wood.   |
| 22. Saule-marceau; a deciduous tree                                     | Salix, sp., 6 × 6 × 2                            | a fine-grained, soft, and weak wood; light wood, in bark.   |
| 23. Térébinthe, ou le faux pistachier —                                 | —  | a large tree, 1·3 metre in diameter.  |
| 24. Caroubier —   | Cercis siliquastrum, 8 × 7 × 1                   | in bark; a tree, 9 in. in diameter, from Monzala.   |
| 25. Olivier sauvage —   | Olea, sp., 6 × 6 × 2                             | in bark; a tree, 10 inches in diameter, from Monzala.   |
| 26. Sorbier cornier; a deciduous tree.                                  | Sorbus torminalis, 6 × 6½ × 2½                   | shows a diameter of about 11 inches; in bark; a hard wood.  |
| 27. Arbousier; an evergreen tree  | Arbutus, sp., 6 × 7 × 2                          | shows a diameter of about 12 inches; in bark; a hard wood.  |
| 28. Arbousier —   | Arbutus, sp., 13 × 8½ × 1                        | bark on both longitudinal edges; a tree, 10 inches in diameter, from Monzala.   |
| 29. Cerisier sauvage; a deciduous tree                                  | Prunus, sp., 6 × 6 × 2                           | in bark.  |
| 30. Erable Napolitain; a deciduous tree.                                | Acer, sp., 6 × 4 × 2                             | in bark; shows a diameter of about 5 inches only; a hard wood.  |
| 31. Laurier-rose; a deciduous tree                                      | Neilum (Meander, 8 × 3½ × 2                      | fine and close grain, hard, though light; shows a diameter of about 6 inches; in bark.  |
| 32. Idée; evergreen tree  | Hedera, sp., showing diameter of about 3½ inches | a very light, soft, weak, open-grained wood.  |
| 33. Pin d'Alger; evergreen tree   | Pinus, sp., 6 × 5 × 2½                           | shows a diameter of about 8 inches; in bark; a resinous wood.   |
| 34. Myrte; evergreen tree   | Myrtus, sp., 6 × 3 × 2                           | a fine, close, even-grained wood, hard and ponderous; in bark.  |
| 35. Prunellier sauvage; a deciduous tree.                               | Prunus, sp., 6 × 3 × 1½                          | a fine, close-grained, hard, and rather heavy wood; in bark.  |

## WOODS OF ALGERIA—continued.

37. Genévrier à feuilles de cèdre; an evergreen tree. — Juniperus, 6 × 3½ × 2; shows a diameter of about 4 inches. Alburnum pure white, duramen dark chestnut; in bark; a resinous wood.
38. Houx; an evergreen tree. — Ilex, sp., 6 × 3 × 2, in bark; shows a diameter of about 4 inches; a hard wood.
39. Laurier-sancé; an evergreen tree. — Laurus, sp., 6 × 5 × 2; a light, soft, weak, open-grained wood; in bark.
40. Sumac des corroyeurs; an evergreen tree. — — 6 × 2 × 1½; moderately hard, though light, weak, and open-grained; in bark.
41. Aubépine; a deciduous tree. — Crataegus, sp., 6 × 6 × 2; a fine, close-grained, hard, and rather heavy wood; in bark.
42. Nerprun alaterné; an evergreen tree. — Rhamnus Alaternus, 6 × 5 × 2. A hard, and heavy, though open-grained wood; alburnum fine citron-yellow; duramen dark red-brown; in bark; shows a diameter of about 6 inches.
43. Citronnier; an evergreen tree. — Citrus Limonium, 6 × 2½ × 1½; shows a diameter of about 3½ inches; in bark; a hard wood.
44. Oranger; an evergreen tree. — Citrus Aurantium, 6 × 5 × 2; shows a diameter of about 10 inches; in bark; a hard wood.
45. Blanc d'Hollande, a deciduous tree. — — 6 × 7 × 2½; a light, soft, weak, and open-grained wood; shows a diameter of about 11 inches; in bark.
46. Chêne à gland doux. — — — — Quercus, sp.
47. Chêne liège. — — — — Quercus Suber.
48. Chêne vert. — — — — Quercus Ilex.
49. Micocoulier. — — — — Celtis.
50. Frêne. — — — — Fraxinus.
51. Orme. — — — — Ulmus.
52. Mûrier blanc. — — — — Morus alba.
53. Jujubier domestique. — — — — Ziziphus.

A numerous series of small specimens of the woods of the Upper Pyrenees, suitable for cabinet-work, is also exhibited (St. UBERG, 1495, p. 1248). They are valuable chiefly as showing the grain and character of the different woods, when polished and varnished, and as employed by cabinet-makers. The Jury awarded a Prize Medal for this collection.

Specimens of acacia wood, as employed for machinery, are exhibited by MOUSSILLAC-AMARD, of La Réole (933, p. 1224); these were deemed worthy of Honourable Mention.

Some very interesting specimens of preserved wood are shown by I. A. BOUCHERIE (1104, p. 1230), in illustration of his process of protecting timber from decay, dry-rot, and the attacks of insects.

The remarkable experiments of Dr. Boucherie, on the absorption of saline and other solutions by trees, are well known, and excited very general interest about ten years since. He has, for a long time, been engaged in an extended and minute series of experiments on wood, the object of which was to ascertain the substance best fitted to preserve timber from decay, and to discover the most economical mode of practically applying it on the large scale. The peculiar feature of Dr. Boucherie's original process consisted in the mode in which he availed himself of the vital power of the tree; for, following up the suggestions of Hales, Duhamel, and others, he arrived at the conclusion that it is far easier to impregnate wood with any desired solution when the plant is still full of its own natural juices, and when freshly cut down, than it is when the vessels have begun to contract, and a considerable portion of the natural humidity of the wood has evaporated. In the first instance, indeed, he endeavoured to impregnate the wood of the tree whilst still in a growing state, causing it to suck up various solutions, by means of the absorbing power of the leaves themselves; a process which, however, for various practical reasons, he subsequently abandoned; and, at the present time he adopts a cheap, simple, and effective process for impregnating the felled timber with the preserving liquid, designated in France, "trait de scie, et la craise fonlante." The trunk of the newly-felled tree is cut into a length suitable for two railway sleepers; it is then very nearly divided across, just in the centre, by means of a saw, so as to form a channel, or small reservoir, in the very centre of the log, by means of which the preserving liquid may pass right and left, towards either end; the opening of the saw-cut is then carefully closed all round, and a small flexible tube being introduced into the upper part, serves to convey into the cut the preserving liquid, which, as it is taken up through the flexible tubes, under the pressure of a column of some feet in height, is rapidly disseminated throughout the entire substance of the wood. The preserving liquid which Dr. Boucherie employs, and which from his numerous experiments he considers the best, is

a solution of sulphate of copper. When he desires to increase the hardness of the wood, he uses a solution of pyrolignite of iron; and when his object is to render it flexible, elastic, and at the same time incombustible, he employs a solution of chloride of calcium. By the above-mentioned process, Dr. Boucherie has prepared many thousands of railway sleepers with sulphate of copper, and some which have been down on the Great Northern Railway of France, for five years, are at the present time perfectly sound; whilst similar ones, not prepared, which have been on the same line, are completely destroyed. The Jury, appreciating the very long and laborious series of experiments made by Dr. Boucherie, and satisfied with the successful issue to which he has now brought them, awarded him a Prize Medal for the process.

Specimens of wood for sounding-boards of musical instruments are exhibited by J. HENSTEN, of Lindberg, near Linsell, in Bavaria (76, p. 1101); these were deemed worthy of Honourable Mention.

A collection of woods, extremely well-selected and arranged, is exhibited by Professor NÖRDLINGER, of Hohenheim, Stuttgart (4, 11, pp. 114, 115). These specimens are exceedingly well prepared, so as to show all the chief characters of each wood; though small, each sample is left in the bark, and good microscopic sections accompany each wood. As a small collection, it is admirable, and the Jury accordingly awarded a Prize Medal for it.

A comparatively small number only of Portuguese woods are exhibited; and with one exception, none of them are of very great importance. The Marquis de LOULÉ (553–578, p. 1314), contributes a small collection of 24 specimens, consisting of pine, plum, filbert, wild olive, chestnut, wild pine, elm, mulberry, olive, beech, ash, cherry, cypress, carib-wood, cork-tree, holm, poplar, oak, plantain, white acacia, walnut, orange, box, and crataegus. For these the Jury awarded a Prize Medal.

Other specimens of the ordinary woods are contributed from the Royal Arsenal, from the Ceira Forests, by A. P. F. VAZ (580, p. 1314), and by the Marquis of FICALHO (552, p. 1314).

Three specimens of wood from Angola and Goa are shown, namely, Tacula-wood from Angola, and teak-wood and acro-wood from Goa. The former, exhibited by the GOVERNOR of ANGOLA (590, 1850, p. 1340), is a very remarkably beautiful wood, and which may fairly be called one of the most handsome cabinet-woods known. The Jury accordingly awarded a Prize Medal for this specimen.

A very small number only of Russian woods are shown: a good series of the chief timber trees of the Governments of Grodno, Minsk, and Volhynia are exhibited by A. KAUFMANN (117, p. 1370). For these the Jury awarded a Prize Medal.

Specimens of Rhododendron-wood, and plane-tree wood

are shown from Osoorget by the GOVERNMENT of COPTAIS (118, p. 1870), and of walnut and beech-wood, from Diabolocan by the GOVERNMENT of TIFLIS (119, p. 1870). These were each deemed worthy of Honourable Mention.

No Spanish woods are exhibited; but in the Spanish Department there are two interesting and extensive collections of the woods of Cuba and the Philippine Islands. The series of the woods of Cuba, used for building, furniture, &c., is 225 in number, and is exhibited by the CABINET BOTANICAL GARDEN of MADRID (186, pp. 1340,

1341); the specimens are all cut into the form of books, so as to show the structure of the wood in different sections, and varnished so as to bring out the colour and grain; the latter circumstance, however, though useful in showing the beauty of the wood, renders it rather more difficult to judge of the characters. This collection was formed by D. Ramon de la Sagra, and the woods are described in his large work on Cuba; the following list contains only those woods the botanical names of which have been made out. For this collection the Jury awarded a Prize Medal.

## WOODS OF CUBA.

|                           |       |                                   |       |  |
|---------------------------|-------|-----------------------------------|-------|--|
| 1. Abey macho             | - - - | Jacaranda Sagrana. D. C.          | - - - | A hard wood, the leaves eaten by cattle.                         |
| 2. Abey hembra            | - - - | Pappigia celsa. Rich.             | - - - | A hard wood, the leaves eaten by cattle.                         |
| 3. Acana                  | - - - | Sideroxylum pallidum. Spr.        | - - - | Very dense wood, the fruit eaten by animals, especially by pigs. |
| 4. Agracajo               | - - - | Ardisia cubana. Alph. D. C.       | - - - | Hard wood.   |
| 5. Agracajo carbonero     | - - - | Excocaria (?)                     | - - - | Hard wood.   |
| 6. Aguedita               | - - - | Pteranmia pentandra. Sw.          | - - - | Hard wood.   |
| 7. Almendro               | - - - | Laplacea Curtysana. Rich.         | - - - | Hard wood.   |
| 8. Almendro silvestre     | - - - | Dipholis salicifolia. Alph. D. C. | - - - | Hard wood.   |
| 9. Arara                  | - - - | Bucida Buceras. Lin.              | - - - |  |
| 10. Arbol del cuerno      | - - - | Acacia cornigera. Lin.            | - - - |  |
| 11. Ateje hembra          | - - - | Cordia Valenzuelana. Rich.        | - - - | A hard wood; the fruit eaten by animals, especially by pigs.     |
| 12. Ayua amarilla         | - - - | Zanthoxylum bombacifolium. Rich.  | - - - |  |
| 13. Ayua macho            | - - - | Z. lanceolatum. Poir.             | - - - | Yields gum or resin.   |
| 14. Ayua hembra           | - - - | Z. juglandifolium. D. C.          | - - - | Yields gum or resin.   |
| 15. Azucarero de montaña  | - - - | Icica Edwigia. Rich.              | - - - | Yields gum or resin.   |
| 16. Baga                  | - - - | Anona palustris. Lin.             | - - - | Fruit eaten by animals, especially by pigs.                      |
| 17. Beria                 | - - - | Cordia geracanthoides. Kunth.     | - - - | Hard wood.   |
| 18. Bijaguara             | - - - | Colubrina ferruginea. Brong.      | - - - | Hard wood.   |
| 19. Boniato amarillo      | - - - | Neotandra bopiato. Rich.          | - - - | Both leaves and fruit eaten by cattle.                           |
| 20. Boniato blanco        | - - - | Oreodaphne? alba. Rich.           | - - - | Both leaves and fruit eaten by cattle.                           |
| 21. Brasil                | - - - | Casalpinia bijuga. Sw.            | - - - | A dye-wood.  |
| 22. Brasilete colorado    | - - - | C. horrida. Rich.                 | - - - | A dye-wood.  |
| 23. Bucare                | - - - | Casalpinia crista. Lin.           | - - - | Leaves eaten by cattle.  |
| 24. Cabo de hacha         | - - - | Erythrina umbrosa. Kunth.         | - - - | Hard wood.   |
| 25. Caja                  | - - - | Trichilia spondioides. Jacq.      | - - - | Hard wood.   |
| 26. Caimito               | - - - | Schmidelia nervosa. Rich.         | - - - | Very dense wood; fruit eatable.                                  |
| 27. Caimitillo            | - - - | Chrysophyllum cainito. Lin.       | - - - | Very dense wood; fruit eatable.                                  |
| 28. Canela blanca         | - - - | C. microphyllum. D. C.            | - - - | Hard wood.   |
| 29. Caoba                 | - - - | Canella alba. Murray.             | - - - | Very dense wood.   |
| 30. Carne de doncella     | - - - | Swietenia mahogany. Lin.          | - - - |  |
| 31. Cedro                 | - - - | Byrsonema lucida. Kunth.          | - - - |  |
| 32. Ceiba                 | - - - | Cedrela odorata. Lin.             | - - - |  |
| 33. Ceibon de arroyo      | - - - | Eriodendron anfractuosum. D. C.   | - - - |  |
| 34. Chicharron            | - - - | Pachira emarginata. Rich.         | - - - | Very dense wood.   |
| 35. Cigua                 | - - - | Chicharronia intermedia. Rich.    | - - - | Fruit eaten by animals.  |
| 36. Ciguaraya             | - - - | Neotandra cigua. Rich.            | - - - | Hard wood.   |
| 37. Ciruelo               | - - - | Trichilia havanensis. Jacq.       | - - - | Yields a gum or resin; fruit eaten by animals.                   |
| 38. Cocuyo                | - - - | Spondias purpurea. Lin.           | - - - | Very dense wood.   |
| 39. Copal                 | - - - | Bumelia nigra. Sw.                | - - - | Yields a gum or resin.   |
| 40. Copey                 | - - - | Icica copal. Rich.                | - - - | A dye wood.  |
| 41. Cordoban              | - - - | Clusia rosea. Lin.                | - - - |  |
| 42. Cuaba amarilla        | - - - | Miconia pyramidalis. D. C.        | - - - |  |
| 43. Cuaba blanca          | - - - | Amyris maritima. Jacq.            | - - - |  |
| 44. Cuyani                | - - - | A. sylvatica. Jacq.               | - - - |  |
| Curban, V. Canella blanca | - - - | Cerasus occidentalis. Loiseleur   | - - - | Very dense wood.   |
| 45. Dagame                | - - - | Calyophyllum candidissimum        | - - - | Very dense wood.   |
| 46. Dagulla               | - - - | Lagetta linteraria. Juss.         | - - - | Bark yields a fibre.   |
| 47. Ebano                 | - - - | L. Valenzuelana. Rich.            | - - - | Very dense wood.   |
| 48. Encina                | - - - | Diospyros (?)                     | - - - | Hard wood; fruit eaten by animals.                               |
| 49. Frjolillo             | - - - | Quercus (?)                       | - - - | Very dense wood; fruit eatable.                                  |
| 50. Fustete               | - - - | Lonchocarpus latifolius. Kunth    | - - - | Dye wood.  |
| 51. Gía blanca            | - - - | Broussonetia tibetana. Kunth.     | - - - |  |
| 52. Gía brava             | - - - | Casaria alba. Rich.               | - - - |  |
| 53. Gíao                  | - - - | C. ramiflora. Vahl.               | - - - | Very dense wood.   |
| 54. Gíao de costa         | - - - | Commocladia dentata. Jacq.        | - - - | Very dense wood.   |
| 55. Granadillo            | - - - | Rhus Metopium. Lin.               | - - - | Very dense wood.   |
| 56. Guacima amarilla      | - - - | Brya Ebenus. D. C.                | - - - | Hard wood.   |
| 57. Guacima baria         | - - - | Luhes platyptera. Rich.           | - - - | Dense wood; fruit eaten by animals.                              |
| 58. Guacimilla            | - - - | Xylopia Cubensis. Rich.           | - - - | Fruit eaten by animals, especially by pigs.                      |
| 59. Guacimilla de costa   | - - - | Celtis macrophylla. Kunth.        | - - - |  |
| 60. Guaguac               | - - - | C.avigata. Willd.                 | - - - |  |
| 61. Guama                 | - - - | Prockia Crucis. Lin.              | - - - |  |
| 62. Guama de costa        | - - - | Pastia apicala. Jacq.             | - - - | Hard wood; yields a gum or resin.                                |
| 63. Guapa                 | - - - | L. longifolia. Rich.              | - - - |  |
|                           | - - - | L. crenata. Rich.                 | - - - |  |
|                           | - - - | Lonchocarpus sericeus. Kunth.     | - - - | Bark used for tanning.   |
|                           | - - - | Malvaceo (?)                      | - - - | Bark used for tanning.   |
|                           | - - - | Malvaceo (?)                      | - - - |  |

WOODS OF CUBA—continued.

|   |                                    |   |
|---|------------------------------------|---|
| 64. Guara                                 | Cupania glabra. Sw.                | Hard wood; fruit eaten by animals.                        |
|   | C. tomentosa. Sw.                  |   |
|   | C. crenata. C. triquetra. Rich.    |   |
| 65. Guara colorada                        | Cupania macrophylla. Rich.         | Hard wood; fruit eaten by animals.                        |
| 66. Guavico                               | Xylopia obtusifolia. Rich.         | Very dense wood.  |
| 67. Guayabo agrio                         | Psidium pomiferum. Lin.            | Hard wood; bark used for tanning; fruit eaten by animals. |
| 67. Guayabo silvestre                     |                                    |   |
| 68. Guayabillo                            | Eugenia guayabillo. Rich.          | Very dense wood.  |
| 69. Guayacan                              | Guaiacum officinale. Linn.         | Very dense wood.  |
| 70. Guayacancillo                         | Guaiacum verticillatum. Ortega     | Very dense wood.  |
| 71. Guimbá, V. Guavico                    |                                    |   |
| 72. Guira cimarrona                       | Crescentia acuminata. Kunth.       |   |
| 73. Guira criolla                         | Crescentia cujete. Lin.            |   |
| 74. Ilucso                                | Drypetes alba. Polt.               | Very dense wood; leaves eaten by animals.                 |
| 75. Jaboncillo                            | Sapindus saponaria. Lin.           |   |
| 76. Jagua                                 | Genipa americana. Lin.             | Fruit eaten by animals.                                   |
| 77. Jaguey hembra                         | Ficus (?)                          | Bark used for tanning.                                    |
| 78. Jaguey macho                          | Ficus populnea. Wild.              | Bark used for tanning.                                    |
|   | Erythroxylum brevipes L. C.        |   |

|   | <i>Columbina reclinata</i> . Brong.  | -     |   |
|   | <i>Erihalis fruticosa</i> . Lin.     | - -   | Hard wood.                                |

The series of woods of the Philippine Islands, exhibited by the ECONOMICAL SOCIETY of MANILA (187, p. 1341), consists of 243 specimens. It is very much to be regretted that this collection is unaccompanied by any list, or catalogue, which would have very greatly increased its value. It was, however, deemed worthy of Honourable Mention.

Specimens of St. Domingo mahogany and satin-wood are contributed by Sir R. Schomburgk (1429), H. M. Consul to the Dominican Republic; these form part of the series of raw produce of that country, for which the Jury awarded a Prize Medal (see p. 71).

A few specimens of timber from Tabarca are shown in the collection of Tunis raw produce.

## WOODS OF TURKEY.

A valuable series of some of the chief woods of Turkey are exhibited; the specimens are large and capital, but they are shown in the rough, so that the nature and characters of each wood can scarcely be distinguished the following are the chief woods shown:—

|                     |                             |     |  |
|---------------------|-----------------------------|-----|--|
| 1. Ardji aradji     | <i>Fagus sylvatica</i>      | - - | Used for ship-building and for wheels. |
| 2. Armod aradji     | <i>Pyrus communis</i>       | - - | Common furniture wood.                 |
| 3. Boaz guurgang    | <i>Carpinus betulus</i>     | - - | Fire-wood; rough work.                 |
| 4. Djinnak aradji   | <i>Acer pseudo-platanus</i> | - - | Furniture wood.                        |
| 5. Djinnar aradji   | <i>Fraxinus excelsior</i>   | - - | Furniture and house-work.              |
| 6. Djinnar aradji   | <i>Acer</i> , sp.           | - - | Used for furniture.                    |
| 7. Eiklael aradji   | <i>Sorbus domestica</i>     | - - | Used for grafting.                     |
| 8. Guurgang aradji  | <i>Fagus</i> , sp.          | - - | Fire-wood only.                        |
| 9. Iklamoorg aradji | <i>Tilia vulgaris</i>       | - - | Used for carving and fine work.        |
| 10. Jeeviz aradji   | <i>Juglans regia</i>        | - - | Furniture wood.                        |
| 11. Kawak aradji    | <i>Populus nigra</i>        | - - | Used for house-building.               |
| 12. Karrar aradji   | <i>Ulmus excelsa</i>        | - - | Used for common carpentry.             |
| 13. Keerasje        | <i>Prunus cerasus</i>       | - - | Furniture wood.                        |
| 14. Maatsché aradji | <i>Quercus rubra</i>        | - - | Useful timber.                         |
| 15. Pfundook aradji | <i>Corylus Avellana</i>     | - - | Used for pipe-stems.                   |
| 16. Taphzoos        | <i>Taxus baccata</i>        | - - |  |
| 17. Tozham aradji   | <i>Pinus Picca</i>          | - - | Timber for general purposes.           |
| 18. Zugunt          | <i>Salix alba</i>           | - - | Used for light house-work.             |

Besides these, specimens of *Pinus orientalis*, from Damascus; *Quercus agrilops*, from Litchkofcha and Wallachia; *Juniperus communis*, from Smyrna; *Juglans regia*, from Damascus; *Quercus coccinea*, from Rhodes; *Morus alba*, from Damascus, &c., are also exhibited.

## WOODS OF TUSCANY.

A valuable and excellent collection of Italian woods is exhibited by the ROYAL TECHNOLOGICAL INSTITUTE OF TUSCANY (47, p. 1294), forming part of the series of Tuscan raw produce, for which the Jury awarded a Prize Medal (see p. 71). The collection consists of two series; the one being of furniture or ornamental woods, the other of timber trees, or woods of construction so cut as to show the character of the wood in the best and most instructive manner; several of the woods are scarce and highly interesting. The collection comprises panel and block specimens.

Panel specimens 2 feet long, varying from 15 inches to 20 inches in width, quarter-inch thick, consisting, in most cases, of pieces joined together longitudinally to display to the best advantage the colour and markings of the woods, and affording satisfactory evidence of their fitness for ornamental purposes:—

|                                   |                                 |
|-----------------------------------|---------------------------------|
| 1. <i>Acacia salicifolia</i>      | <i>Gaggia alba</i> .            |
| 2. <i>Acer negundo</i>            | <i>Negundo</i> .                |
| 3. <i>Fagulus hippocastanum</i>   | <i>Castagno Italia</i> .        |
| 4. <i>Ailanthus glandulosus</i>   | <i>Ailanto</i> .                |
| 5. <i>Alnus cordifolia</i>        | <i>Ontano Napoletano</i> .      |
| 6. <i>Betula alba</i>             | <i>Betula</i> .                 |
| 7. <i>Broussonetia papyrifera</i> | <i>Moro papirifero</i> .        |
| 8. <i>Cercis canadensis</i>       | <i>Siliquastro del Canada</i> . |
| 9. <i>Cereis siliquastrum</i>     | <i>Siliquastro</i> .            |
| 10. <i>Cotinus laburnum</i>       | <i>Maggio piodolo</i> .         |
| 11. <i>Diospyros lotus</i>        | <i>Lofo</i> .                   |
| 12. <i>Elaeagnus hertensis</i>    | <i>Olivo di Boemia</i> .        |
| 13. <i>Fraxinus americana</i>     | <i>Frassino Americano</i> .     |
| 14. <i>Fraxinus sambucifolia</i>  |                                 |
| 15. <i>Gynocladus canadensis</i>  | <i>Albero morto</i> .           |
| 16. <i>Juglans nigra</i>          | <i>Noce nero</i> .              |
| 17. <i>Keteleeria paniculata</i>  |                                 |

|                                 |                                |
|---------------------------------|--------------------------------|
| 18. <i>Melia Azadirachta</i>    | <i>Albero di Zaccheo</i> .     |
| 19. <i>Olea europaea</i>        | <i>Olivo</i> .                 |
| 20. <i>Pinus cedrus</i>         | <i>Cedro del Libano</i> .      |
| 21. <i>Platanus orientalis</i>  | <i>Platano orientale</i> .     |
| 22. <i>Prunus lauro-cerasus</i> | <i>Lauro-ceraso</i> .          |
| 23. <i>Prunus mahaleb</i>       | <i>Albero di Santa Lucia</i> . |
| 24. <i>Rhamnus alaternus</i>    | <i>Alaterno</i> .              |
| 25. <i>Rhus typhina</i>         | <i>Somacco</i> .               |
| 26. <i>Robinia pseudacacia</i>  | <i>Acacia, or Cascia</i> .     |

Block specimens, consisting of branches and trunks, cut in half, showing bark, longitudinal section, and oblique transverse section:—

|                                  |                     |
|----------------------------------|---------------------|
| 27. <i>Acacia lophantha</i>      |                     |
| 28. <i>Acer campestre</i>        | <i>Leppo</i> .      |
| 29. <i>Acer negundo</i>          | <i>Negundo</i> .    |
| 30. <i>Acer pseudo-platanus</i>  | <i>Acero fico</i> . |
| 31. <i>Ailanthus glandulosus</i> | <i>Ailanto</i> .    |
| 32. <i>Amyris polygama</i>       |                     |
| 33. <i>Betula alba</i>           | <i>Betula</i> .     |
| 34. <i>Buxus sempervirens</i>    | <i>Bossolo</i> .    |
| 35. <i>Carpinus betulus</i>      | <i>Carpino</i> .    |
| 36. <i>Castanea vesca</i>        | <i>Castagno</i> .   |

## WOODS OF TUSCANY—continued.

|                             |       |                       |
|-----------------------------|-------|-----------------------|
| 37. Celtis australis        | - - - | Giracole.             |

Some very excellent venours of walnut-wood, cut in a peculiar manner, invented by the exhibitor, are shown by A. DUCCI, of Florence (99, p. 1298). The Jury awarded a Prize Medal for these.

## VIII. MISCELLANEOUS SUBSTANCES.

Under this head are classed those vegetable substances not properly coming under any of the preceding divisions. It would have been easy to have included in it a very large number of new and little-known products, and of substances chiefly interesting as curiosities; the Jury, however, considered that in so doing they would merely increase the length of their Report, without leading to any practical result; they have therefore entirely omitted all mention of these substances, and simply here refer to one or two articles especially deserving of notice.

A very beautiful collection of anatomised plants, flowers, and leaves, is exhibited by E. KING (2, p. 195). In these remarkable dissections, the whole of the soft and pulpy matter of the plants is removed, and only the woody or fibrous part is left, forming a perfect net-work of woody tissue. This effect is produced by steeping the plants in rain-water, in which they are suffered to remain until the whole of the soft parts are decomposed; they are then placed in fresh water and the decomposed matter carefully removed with a brush; after this the remaining fibrous part is bleached in a weak solution of chloride of lime and then dried. The time required for this operation varies from a few weeks to several months, and its success essentially depends on the minute and patient care bestowed on the brushing away of the de-

composed pulpy matter. The specimens exhibited by E. KING are remarkable for their beauty and the very perfect manner in which the whole of the woody skeleton of the plants has been preserved; the Jury, accordingly awarded a Prize Medal for them.

Some excellent specimens of similar anatomised plants are likewise contributed by Lieut. TILLEY (5A, p. 195\*). These were deemed deserving of Honourable Mention.

Various small collections of dried or preserved plants and flowers are shown by different exhibitors; namely, preserved flowers intended as botanical illustrations, by W. STEVENS (3, p. 195\*); preserved pitcher plants, by E. W. COOKE (2A, p. 195\*); dried mosses, by M. ROCK (5, p. 195\*); and dried mosses and sea-weeds by E. HOLT (128, p. 205\*).

A series of well-prepared and carefully-dried ferns from Madeira is contributed by GENOVEVA GONCALVES (21B, p. 1319); this was deemed worthy of Honourable Mention.

Finally, the Jury would specify in this department, as deserving of Honourable Mention, the specimen of selected tangles for the use of wool-dressers, exhibited by ROTSCH and REICHEL, in the Austrian Department (98, p. 1012).

EDWARD SOLLY, REPORTER.

London, February 1852.

## PART II.—ANIMAL KINGDOM.

## A.—FOR TEXTILE FABRICS AND CLOTHING.

## WOOL.

The raw material of most importance and in most general use for the above purposes is WOOL. This is a peculiar modification of hair, presenting, when viewed under the microscope, fine transverse or oblique lines, from 2,000 to 4,000 in the extent of an inch, indicative of an imbricated scaly surface, on which, and on its curved or twisted form, depends its remarkable felting property and its consequent value in manufactures.

Most quadrupeds possess the woolly variety of hair as an under-clothing, but in a small proportion, and hidden by the smooth, exterior, coarser, and straighter kind of hair. In the wild sheep (*Ovis montanum* and *Ovis musimon*) the woolly variety of hair is developed in excess; and in the domesticated breeds the fleece has been modified and improved, in various degrees, by crossing the breeds, choice of climate and pasture, and careful attention and defence during its growth, until not only has the original coarse character of the product disappeared, but qualities of wool of different kinds and of different degrees of superiority have been obtained, which are generally divisible into two classes—the one better adapted for “carding,” the other for “combing,” and both available for a great variety of useful and elegant textile fabrics.

In judging of these qualities in the wools exhibited, the Jury have tested the fineness and elasticity of the fibre; the degrees of imbrication of the scaled surface of the fibre as shown by the microscope; the quantity of fibre developed in a given space of the fleece; the comparative freedom of the fleece from extraneous matters; and the skill and care employed in preparatory processes; such, for example, as that termed “scouring” the fleece, upon which depends its liability, or otherwise, to mat at the bottom of the staple.

In these examinations the Jury have to acknowledge the valuable aid of well-versed English and Foreign Experts.

After the comparison of the wools exhibited by the growers of different nations, the Jury are unanimous in making the first mention of those transmitted from Germany, as being pre-eminent in the qualities of highest value.

Under “German Wools” are included those from Austria and Austrian Silesia, Hungary, Prussia, Saxony, and Polish Silesia.

## Austria.

FRIDON and SONS (90, p. 1012).—The fleeces exhibited by this firm present, in a high degree, the desired qualities of substance in the staple, and of fineness and elasticity

of the component fibres, the spiral curves of which are close and regular, and are immediately resumed after being obliterated by stretching the fibre,—the length of which is also considerable for wool of this "carding" quality, the most valuable for the finest descriptions of cloth. One of the Experts in wool characterises the specimens, exhibited by Messrs. Figdor and Sons "as a superior and high-bred wool—the finest and most legitimate specimen in the whole Exhibition." The degree of superiority over some of the wools in the same department, which was contested by another Expert, was admitted by the first to be slight; whilst opinions were unanimous as to the superior character of the wools, generally, from Austrian Silesia and Hungary. The Jury, therefore, appreciating the difficulty of arriving at a correct judgment of the degrees of individual merit, especially from samples giving an uncertain indication of the average value of the produce of flocks, came to the conclusion of recommending the award of the Council Medal, as notified in the Second Section of the Report, so as to signify their appreciation of the highest class of wools; and to distinguish the manifestly superior qualities of the wools exhibited by individuals by the award of the Prize Medal; and they place first on the list the firm of MM. ISAAC FIGDOR and Sons, of Vienna.

COUNT H. LARISCH MOENNICH (92, p. 1012).—The product of a fine and well-known flock, from Silesia, is exhibited by four fleeces, which present similar excellent qualities to those of No. 90, the difference, on the whole, being so slight that the Jury also award the Prize Medal to COUNT H. LARISCH MOENNICH, of Silesia.

COUNT ANTON VON MITTROWSKY (91, p. 1012).—These fine and high-bred fleeces of a pure merino flock, from Silesia, exhibit the valuable qualities of fineness and elasticity of fibre in so eminent a degree that the Jury award the Prize Medal to their exhibitor.

COUNT JOSEPH HUNYADY VON KETHELEY (89, p. 1012).—The fleece, from a flock in Hungary, is an unwashed specimen, but of a very fine quality of fibre; it is a little inferior to the best Silesian examples only in being somewhat thinner or poorer in substance. The fine imbrication and elastic properties of the fibre are, however, so remarkably characteristic of this fleece, that the Jury award to its exhibitor the Prize Medal.

The washed and unwashed wools exhibited by COUNT O. VON WALLIS (93, p. 1012) (Bohemia), and by Messrs. PANNA and ALEXIS, (94, p. 1012) (Transylvania), present qualities which entitle them to Honourable Mention.

#### Zollverein.

W. GRAFF (803, p. 1094).—The fleece of wool exhibited on a stuffed sheep from the merino flock of this exhibitor, at Münchenhoff, merits, from the fineness and closeness of the fibre and its excellent "carding" qualities, the award of the Prize Medal.

LEGATIONS-RATH KUEPPER (29, p. 1049).—The merino fleeces of two-year old ewes, from Bromberg, here exhibited, are remarkable for the fineness and regularity of the staple, and illustrate favourably the advance of the improvement of wool in the Prussian districts of the Middle Vistula: the Jury deem them to merit the award of the Prize Medal.

E. LUBBERT (24, p. 1049).—The fleeces transmitted by this exhibitor from Zweybrodt, near Reglau, are very remarkable for those qualities which, li. of the Austrian-Silesian wools, adapt them for the fabrication of the finest cloths, and the Jury award to Mr. LUBBERT the Prize Medal.

G. L. NORDMANN (30, p. 1049).—The fleeces from Liszkowy, near Mowraglaw, are also fine specimens of Prussian wools, remarkable for the great regularity in the staple, and meriting the award of the Prize Medal to M. NORDMANN.

• OBERBURGGRAF VON BRUNNECK (45 and 46, p. 1050).—The fleeces of a ram and a ewe from a merino flock at Bellachwitz, and the specimens of wool indiscriminately taken from a merino flock at Rosenberg, though rather inferior in quality to the finest Silesian wools, manifest a fineness, softness, and elasticity of fibre

and a regularity of staple which, in the opinion of the Jury, merit an award to the exhibitor of the Prize Medal. The Bellachwitz flock was procured by the Oberburggraf in Spain in 1814, and afterwards improved by additions of the finest Saxon and Silesian races in 1820 and 1824.

M. OCKEL, for the ROYAL ADMINISTRATION OF FRANKENFELDE (27, p. 1049).—The fleeces of a ram and of ewes shorn in the spring of 1850, and the samples of wools from the flocks kept at Wrietzen on the Oder, under the above Administration, manifest qualities which the Jury have considered to entitle the Administration to the award of the Prize Medal.

Of other exhibitors of wools in the Zollverein, BARON ECKARDSTEIN (32, p. 1049), on account of the regularity of the staple in two examples of wool in fleeces; COUNT VON SCHWERIN (33, p. 1049), for the fleeces of a ram and ewe of the Saxon breed, remarkable for their fine qualities as "combing wool;" FLOCKENHAUS and Co. (335, p. 1070); BARON VON LUTTWITZ (42, p. 1050); R. LEHMANN (47, p. 1050), for fleeces of fine raw wool; A. P. THAER (23, p. 1049), for the richness of the staple and fineness of the hair; MM. PÉLL & Co., of Düren\* (369, p. 1071); M. A. VON SAUKEN (433, p. 1075); BARON S. VON LOTHSCCHILD (280, p. 1049), for four fleeces of fine merino wool, from a flock of 15,000 head at Schillersdorf; J. VON LIPSKE (25, p. 1049), for a ram's fleece from the owner's flock at Ludomy; — HEY (26, p. 1040), for the fleeces of wool from the flock of the Electoral race, under the personal superintendence of the exhibitor at the Royal Domain of Hainsburg, Saxony; and the fleeces exhibited by the ROYAL REMOUNTING HORSE-DEPÔT (22, p. 1049), on account of the weight of the wool and the length and resistance of the fibre, which adapt it for combing; are severally deemed by the Jury to be worthy of Honourable Mention.

#### United States of America.

Mr. COCKERILL.—The wool transmitted by this exhibitor from Northville is well got up, and exhibits, like the preceding specimens, a quality of fibre, indicative of care and skill in the development and improvement of the fleece, which calls for the award of the Prize Medal.

Mr. J. H. EWING (188, p. 1449).—The wool, transmitted from Washington, Pennsylvania, by this exhibitor, is remarkable for the good substance of the fleece, as well as for the quality of the fibre, and the Jury award to him the Prize Medal.

Messrs. KIMBER and Co. (500, p. 1466).—The specimens of fine clothing wool, exhibited by this firm, also develop qualities which merit, in the opinion of the Jury, an award of the Prize Medal.

Messrs. PERKINS and BROWN (201, p. 1449).—The samples of fine combing wool transmitted from Ohio exhibit qualities which merit the award of the Prize Medal.

Among the samples of American wools deserving Honourable Mention the Jury include—Mr. J. BLAKESLEE, of North Castle, New York (131, p. 1441), samples of merino wools;—Mr. P. A. BROWN, of Philadelphia, Pennsylvania (40, p. 1439);—Messrs. PARKER and BROWN (235, p. 1451), bale of fine wool;—Mr. T. C. PETERS, of Darien, New York (106, p. 1440), specimens of wool of the Saxony breed;—Mr. S. SIMLEY, of Hopkington, New Hampshire (197, p. 1449), sample of wool from a flock of the Saxony breed. One of the able Experts, whose valuable aid the Jury have already acknowledged in their examinations of the wools, reports "those shown by America as most approximating to the character of the German wools."

#### Russia.

N. N. SCHLOSS-TRIKATEN (128, p. 1370).—The specimens of wool from Livonia here exhibited appear to be derived from a flock of Silesian origin, and manifest all these characters of the fibre which adapt it for good clothing purposes; and the Jury award to the exhibitor an Honourable Mention.

Among other examples of wool of a good and valuable

\* This Firm's name is inserted in the Award List of Class XII.

quality in the Russian Department, the Jury select, as deserving Honourable Mention—**T. GAMALEY**, of Bessarabia, district of Ackerman (122, p. 1370), samples of the merino breed;—**VASSAL**, of Tauride, district of the Daieper (122, p. 1370), specimens of merino wool;—**L. & F. PHILLBERT**, Tauride, district of Melitopol (124, p. 1370), specimens of merino wool;—**A. AKHOONDOFF** **SEAH MIRZA**, of Stavropol, district of Piatigorsk (126, p. 1370), specimens of white and black wool, unwashed;—**S. GIGOLO**, of Gork (130, p. 1370), for specimens of black wool, unwashed;—**THE FARM OF GORIGORETZK**, of Mohileff (121, p. 1370), for specimens of merino wool;—**Mahomet Khan YOUSSEF**, of Derbent, in the Khanate of Kiurin (129, p. 1370), for specimens of white wool, unwashed;—**J. ABRAMOFF**, of Ekaterinoslaw (131, p. 1370), for his examples of fine unwashed Cashmere goats' hair;—and **L. K. NARISHKIN**, Saratoff, district of Balashoffsk.

#### France.

**J. L. GRAUX** (245, p. 1188).—Council Medal. The specimens of the new variety of wool exhibited by M. Graux, and which have been deemed worthy of the recommendation of the Council Medal, have already been noticed in the Second Section of the Report.

**LE GÉNÉRAL GIROD (DE L'AIN)** (1249, p. 1237).—The fleeces of merino wool, from the exhibitor's flock at Nuz, although of a thin staple, and apparently not full-grown, display the qualities adapting it for the finer descriptions of cloth in so excellent a degree, that the Jury award to Général Girod (de l'Ain) the Prize Medal.

**NATIONAL SHEEP-FOLD OF RAMBOUILLET** (1080, p. 1230).—The qualities of the four fleeces of the true merinos, exhibited by this valuable institution, have also been considered such as to merit the award of the Prize Medal.

**E. LEFÈVRE** (345, p. 1239).—The specimens of wool in tufts transmitted by this exhibitor from Gevrolles (Cote d'Or) are long in the staple and very sound, forming a very superior description of combing wool, and, as such, deserve the award of a Prize Medal.

**F. RICHER** (354, p. 1194).—The two fleeces of rams of pure merino breed, two years old, transmitted from Gouxix, Calvados, have also appeared to the Jury to merit, in the comparison of the wools from France, the award to M. Richer of the Prize Medal.

The exhibitors of wools in the French Department whom the Jury would distinguish by Honourable Mention are—**EELATRE and SON** (142, p. 1178); **MAFORTE and SON** (900, p. 1223); **MM. BRUNEAU and SON** (38, p. 1173); for the specimens of combed wool, spun by an apparatus of the exhibitor's construction, **M. MALINGIE** (322, p. 1192), for the fine combed wool, the produce of a flock reared at the Agricultural School of La Char-moise, Pont Leroy (Loire et Cher); **MM. LAROQUE and JAQUEMET** (901, p. 1223), for their assortment of spun wool for knitting blankets; **G. RIVAUE**, of Petit Rochefort (987, p. 1226), for his good fleeces of merino wool; **V. E. WARMONT** (1048, p. 1229), for his specimens of wool in skeins; **MM. PATURLE-LUPIN SEYDOUX, SEINER, and Co.** (1381, p. 1242), for their samples of cleaned wools; **J. A. LERASSON DE MONTLEAU** (1498, p. 1248), for his fleeces of merino wool; and **MM. BERNOVILLE, LARONNIER, and CHEREST** (1548, p. 1250), for their examples of combed wool and woollen yarn.

#### Spain.

**D. JUSTO HERNANDEZ** (230, p. 1344).—Of black and white wool from Salamanca four samples have been transmitted by this exhibitor:—1. Unwashed wool for clothing purposes; 2. Unwashed wool for worsted; 3. Wool washed before shearing, in the Saxon manner; 4. Wool sheared in February, 1851. M. Justo Hernandez has introduced into Spain the custom of clothing the sheep from the beginning of December to the end of May; and amongst the specimens transmitted to the Exhibition is a fleece which has been so defended, and one that has been exposed to the direct influence of the atmospheric agencies. The difference in the quality is remarkable, and speaks decidedly in favour of a temporary protection of the fleece. The good qualities of most of these

specimens of Spanish wool have appeared to the Jury to merit for D. Hernandez the award of the Prize Medal.

Of other samples of wool transmitted from Spain the Jury select as deserving Honourable Mention—(225, (p. 1343), **S. MONLEAO**, of Seville, for his samples of fine unwashed merino wool; and (226, p. 1343), the PROVINCE of HUELTA, for the good quality of wool exhibited from the flocks fed on the Sierra de Audevalo.

#### United Kingdom of Great Britain and Ireland.

**C. DORRIEN** (17, p. 201\*).—The samples of wool transmitted from Chichester, by this exhibitor, give evidence of a very high-bred flock, and manifest qualities of fibre, for which the Jury award the Prize Medal.

**R. MILLNER** (85, p. 201\*).—The fleeces, showing a long staple, grown in the counties of Meath and Galway, and the long and short wool fleeces of the mountain sheep, county of Wicklow, exhibit qualities of fibre for which the Jury award the Prize Medal.

**J. G. REDOW** (84, p. 201\*).—The specimens of wool from the Southdown breed also exhibit qualities of such excellence as to call for the award of the Prize Medal.

The fleeces of Cheviot wool, grown at an elevation of 2,600 feet above the level of the sea, exhibited by Mr. HENDERSON, of Wooler, Northumberland (80, p. 201\*), are remarkable for the fine silky quality of the fibre, which is well adapted for the blanket manufactory. The Jury regard these specimens as deserving Honourable Mention. The Jury also desire to record Honourable Mention of the fleeces of fine German wools, exhibited by Mr. C. LARREAR, of Leeds, under 97, (p. 201\*); and the series of wools shown by Mr. CHEESEBOROUGH, of Bradford, under 179, (p. 493) Class XII.

An object of curiosity is shown in the English Department, being a Southdown ewe, stuffed, seven years old, which had never been shorn. The weight of the accumulated annual fleeces was 36 lbs. This specimen is exhibited by **Ms. J. MOORE**, of Littlecott Farm, Pewsey, Wilts (78, p. 201).

#### Australia.

**Lieut.-Col. E. MACARTHUR** (13, p. 989, 990).—The case, containing 132 specimens of merino wool, exhibits very favourable examples of the condition of the fleeces of that valuable variety of the sheep in New South Wales. The Jury regret that the quantities transmitted are too small to afford the requisite means of judging of the average qualities of the flocks; but, taking into consideration the important services rendered by Lieut.-Col. Macarthur to the colony by his persevering and successful endeavours to develop a source of wealth from the merino breed of sheep, the Jury award to him the Prize Medal.

The first importation of wool from New South Wales into England in 1807 was 245 lbs. In the year 1848 the quantity from New South Wales, alone, amounted to 23,000,000 lbs., valued at more than 1,200,000l.

The Jury desire to express, by Honourable Mention, their opinion of the good qualities of the wools exhibited

by **Mr. T. LEARMONTE** (6, p. 989), mark ; by

**Messrs. STEVENS and THOMSON** (347, p. 999) ; and

by **Mr. GRANT**, of Tasmania.

#### Cape of Good Hope.

With regard to the wools exhibited from this colony, Nos. 31 and 32 are fine samples, but are too small in quantity to support a judgment as to the average value of the fleeces from the flock. The Jury, however, regard the samples transmitted by **REITZ, BREDA, and Co.** (30, p. 950), and by **D. G. VAN BREDA** (32, p. 950), as deserving Honourable Mention.

The specimens of wool, the production of Cachemere goats kept by His ROYAL HIGHNESS PRINCE ALBERT, at Windsor, and exhibited by His Royal Highness, are examples of an additional staple new to England, and give encouragement by their quality to the repetition of similar efforts to multiply and preserve that remarkable variety of the genus *Capra*. This staple includes, be-

sides the closer and finer hairs answering to the wool of sheep and the fur of other quadrupeds, a coarser or stronger kind of white hairs. Both kinds are of value in manufacture—the stronger hairs, which require to be picked out prior to attempting to manufacture; the finer portions being afterwards used in the fabrication of coarse woollen cloths. This example of European Cashmere wool would have received a Medal from Jury IV. had not one been already awarded to it by the Jury of Class XII.

#### HAIR AND BRISTLES.

##### Russia.

The best developed and most valuable examples of these productions are exhibited in the Russian Department, in which the Jury select—

**RASILE KOUDBIAPEZEFF JADENOFFSKY** (340, p. 1382), for the award of the Prize Medal, merited by the superior qualities of the horse-hair exhibited by him under that number. In the sample of white hair from the tail, the hairs are 40 inches in length, and of the first quality for evenness, elasticity, and shining surface. In the sample of black tails, the hairs are 42 inches in length. Fine specimens of white hair from the mane, of from 28 to 30 inches in length, both transparent and opaque, and good samples of horse-hair for furniture, both drawn and curled, black, grey, and white, are also shown by the above Exhibitor.

Of the samples of bristles exhibited in the Russian Department, the Jury select—

**SEMENOFF and FALEYEFF** (135, p. 1370), as deserving, from the superiority of the combined qualities of strength, elasticity, and fineness of surface, the Prize Medal. These qualities are particularly shown in the packets of the sorted variety called "okátka."

The Jury regard as deserving Honourable Mention the fine-textured and well-formed bristles shown by the peasants **KORIAKIN** and **MOUCIKOFF**, of Vologda, under (134, p. 1370); and the selected bristles, of different qualities, shown by **J. ZOLOTOREFF**, of Kalonga, under 136 (p. 1370); the prepared horse-hair for mattresses, shown by **A. BEZHOUKAVNIKOFF-SOKOLOFF**, under 248, (p. 1374); and the plumes of horse-tails, and black buffalo tails, exhibited by **P. IVANOFF**, of St. Petersburg, under 159, (p. 1375).

##### Belgium.

Among the examples of hair and bristles transmitted from Belgium, the Jury deem worthy of Honourable Mention samples of hogs' bristles, prepared and bleached for painting-brushes, exhibited by **H. HAUSSENS-HAP**,\* of Vilvoorde (257, p. 1159); and the samples of horse-hair, horse-tails and manes, and pigs' bristles, shown by **H. SONZE-MABEY**, of Liège\* (265, p. 1159).

##### Netherlands.

**MM. CATZ and Co.** (30, p. 1144).—Specimens of drawn horse-hair for fiddle-sticks, and horse-hair for stuffing furniture, show qualities deserving Honourable Mention.

##### Zollverein.

**H. FUDIKAR**, of Elberfeld (596, p. 1063). Specimens of horse-hair for upholstery purposes, deserve, for their fine and equal texture and elastic qualities, Honourable Mention; and the Jury also award the same distinction to **GOTTLIEB FORSE†** (813, p. 1095) for his well-selected series of hogs' bristles and picked hogs' hair from Halle.

##### Spain.

**D. D. DELGADO**, of Saragossa (281, p. 1344).—This exhibitor has transmitted some interesting examples of the hair of the rabbit and hare, shaved off the skin by a mechanical process. The vast numbers of these prolific

rodents in Spain would afford a large supply of this kind of hair; and the Jury desire to signify their encouragement and approbation of **D. Delgado's** industry by making Honourable Mention of these specimens.

#### WHALEBONE.

The substance so called is closely analogous, in its chemical and physical properties and mode of growth, to hair and bristles, but is developed in compact plates which resolve into stiff bristles, at their free margin, from the thick gum at the circumference and palatal surface of the upper jaw of the animals of the whale tribe. The most valuable kind of whalebone is obtained from the great Arctic whale (*Balaena mysticetus*), in which the plates or 'blades' are arranged in several rows, the outermost consisting of the longest plates, attaining, in a full grown whale, the length of from 8 to 12 feet.

##### England.

**Mr. HENRY HORAN** (103, p. 201, 202).—This exhibitor shows well-selected examples of whalebone plates from the Arctic whale (*Balaena mysticetus*), which yields the largest and best kind; from the Antarctic whale (*Balaena australis*), which affords the second best kind; and from the great finner whale (*Balaenoptera Boops*), which affords the shortest and coarsest plates. With these examples of the raw material, Mr. Horan exhibits specimens in various states of preparation, and numerous and ingenious applications of the prepared whalebone, of different kinds, as, e.g., for covering whip-handles, walking-sticks, and telescopes, and in the form of shavings for plaiting, like straw, in the construction of light hats and bonnets. The Jury, taking into consideration the illustrative collection of this raw material in connexion with its various applications, adjudge to Mr. Horan the Prize Medal.

**WESTALL and Co.\*** (104, p. 202\*).—The same grounds which are specified in relation to No. 103, sustain the award of the Prize Medal to Mr. Westall, in whose collection the Jury have to specify more especially the great variety of filamentary modifications of the whalebone material for numerous useful applications.

The fine blades of whalebone from the *Balaena mysticetus*, exhibited in the United States Department, under 537, (pp. 1467, 1468), by **Mr. L. GODDARD**, deserve Honourable Mention, as do likewise the specimens of Balen plates from the *Balaena australis*, exhibited by **Mr. S. MOSES**, under No. 237 (p. 997), from Van Diemen's Land.

#### SILK.

The most valuable kind of Silk, and that which is the subject of the most extensive and pains-taking culture, is a secretion of the larva of a species of moth, indigenous to China, called, *par excellence*, the "silk moth," and by entomologists, *Bombyx mori*, from its native and favourite food, the leaves of the mulberry tree. The species was first introduced into Europe in the reign of the Emperor Justinian, by two Nestorian monks who had travelled in China, and who succeeded in bringing a quantity of eggs, secured in a hollow cane, to Constantinople, where they were hatched, and the larvae fed and reared on the leaves of the white mulberry. The breeding of silkworms in Europe was confined for six centuries to the Greeks of the Lower Empire. In the twelfth century the rearing of silkworms and the manufacture of silk were introduced into Sicily; in the thirteenth century into Italy; whence this important branch of industry has been successively established in Spain, France, England, and most of the colonies with a suitable climate.

Silk is a secretion of a pair of long glandular tubes which terminate in a prominent pore or spinneret on the under lip. Before their termination they receive the secretion of a smaller gland, which serves to glue together the fine filaments from the two 'sericteria,' the apparently single thread being in reality double, and its quality being affected by the quality or difference between

\* These exhibitors receive Medals in Classes XVI and XXVIII, in whose Award List their names appear.

† This exhibitor receives a Prize Medal in Class XXVIII, in whose Award List his name appears.

\* These exhibitors receive their Medals in Class XXVIII, in whose Award List their names appear.

the secreting power of the two sericteria. The silkworm commences spinning when it is full grown, in some convenient spot ..... points of attachment for the first-formed thread, which is drawn from one part to the other until the body of the larva becomes loosely enclosed by the thread. The work is then continued from one thread to another, the silkworm moving its head and spinning in a zigzag way, in all directions within reach, and shifting the body only to cover the part which was beneath it. During the period of spinning the cocoon, which usually takes five days for its completion, the silkworm decreases in size and length considerably; then casts its skin, becomes torpid, and assumes the form of the chrysalis.

The main object of the silkworm breeder is to obtain cocoons of a large size, composed of a long, strong, very fine, even, and lustrous thread. These properties of the silk have been realised in the highest degree in the specimens transmitted from France, in which country the development of the silkworm has for a long period exercised the care and pains of many able breeders, and of late years has been the object of systematic advancement by the Central Society of Sericulture of France.

The *Bombyx mori*, having been bred and reared under the special care and management of man during a long succession of ages, may be regarded as a domesticated species of insect; and it has become the subject, as in the higher domesticated races of varieties—of which those called 'Sina,' 'Syrie,' and 'Novi,' in France, are examples.

The 'Sina' variety of the silkworm is known and esteemed for the pure whiteness of its silk, the thread of which is fine, but weak, and not very lustrous. The 'Syrie' variety is of large size, produces a cocoon abundant in silk, but the thread is rather coarse, and inclines to a greenish tint. The 'Novi' race is small, but the cocoons are firm and well made, and the silk is lustrous, but has a yellowish tint.

#### France.

The specimens of silk exhibited in the French Department are numerous, and the degrees of excellence hardly to be discriminated in the finest examples selected for the award of the Prize Medal. In specifying the names of the exhibitors so distinguished, the Jury propose, therefore, to limit themselves to the mention of the more remarkable circumstances which they have found to be associated with certain examples. The Jury select, as the first in order of merit—

Major COMTE DE BRONNO BRONSKI (782, p. 1218), exhibitor of unbleached silk and silk cocoons from the Chateau de St. Selves, near Bordeaux, Department de la Gironde. The cocoons are remarkable for their large size and regularity of form, and the silk for the unusual length of the thread, its natural pure white colour, its fineness and lustre. The circumstances under which this superior quality of silk is obtained are certified—in a Report by a Committee of the Agricultural Society of the Gironde,\* signed Philippin, and dated 25th April 1847—to be as follows:—

In 1836, Major Bronski reared separately the eggs of the three varieties, 'Sina,' 'Syrie,' and 'Novi.' In 1837 he set apart the cocoons of the varieties 'Syrie' and 'Novi,' and on the exclusion of the imago, or perfect insect, he associated the males of the 'Novi' with the females of the 'Syrie'; and the hybrid ova were hatched at the ordinary period in 1838, the same operations being repeated in 1839 and 1840. With regard to the race 'Sina,' M. Bronski, in 1837, separated the white from the black worms as soon as they were hatched. He then selected the largest and best-shaped cocoons, and made a special collection of the eggs from the moths excluded from those cocoons. This procedure was repeated in 1838 and 1839; but in 1840 he associated the males excluded from the large cocoons of the black worms with the females excluded from the largest cocoons of the white worms. In 1841 he associated the males of the 'Sina' race with the hybrid females obtained from the above-described crossings of the 'Novi' and 'Syrie' breeds.

By these and similar experiments M. Bronski at length appears to have succeeded in obtaining a race of silk-

worms not subject to disease, producing a large and equal sized cocoons of a pure white colour, the silk of which is equal in all its length, strong and lustrous, and which is certified to present an average length of thread of 1057 metres (1154 yards English).

The Jury, in awarding the Prize Medal to Major Count Bronski, desire, at the same time, to give expression to their unanimous opinion as to the importance of the resumption, by the highest administrative and scientific authorities in France, of those investigations which had been entered upon with a view to determine the stability and commercial value of the results of M. Bronski's experiments and discoveries in the amelioration of the breed of silkworms.

The French exhibitors of silks of fine qualities are numerous; and amongst these the Jury award the Prize Medal to

MM. ALCAN and LAMET (1050, p. 1229); in regard to whom the Jury desire to express their approval of the new mode of 'filature à froid,' and of the mode of dividing the silk of the pure cocoons of the Indian silkworm (Tussar), both of which improvements are due to MM. Alcan and Lamet.

MM. ARDIN and CHANCEL (8, p. 1170).

C. BILVAIS (1076, p. 1229), to whom the silk-manufacture in France owes much, for his establishment of a school of sericulture, for diffusing the true principles on which the development, breeding, and improvement of the silkworm should be carried on.

L. BONDON (1105, p. 1230).

C. CHAMBOIS\* (113, p. 1196).

JE CHAMPANET SARRAS 114, pp. 1176, 1177.

MM. COUDRE and SOUVERET\* (96, p. 1176).

MM. DROUIN and BROSSIER (169, 1181).

GIRLLIN and SON (816, 1220).

JAMES BRANCH, and DESIGNER (1273, p. 1238).

With this series of cocoons and of raw and thrown silks are associated twenty-five ingenious and elegant figures, of the silk thread as viewed by the solar microscope, in illustration of a valuable memoir by M. Desgeneur, in course of publication at the charge of the Chamber of Commerce and of the Agricultural Society of Lyons.

T. DE THILANCOURT (697, p. 1212).

A. DUCAL (189, p. 1183).

GERIN, MESTVILLE, and ROBERT (784, p. 1218).

LAPIERRE and DOLHAC (1292, p. 1235).

J. MESTRE\* (1057, p. 1256).

L. MOUINS (617, p. 1209).

MM. RIGAUD BROTHERS (1426, p. 1214).

MM. RUS and CO (1464, p. 1246).

L. SOUTHERLAND\* (1190, p. 1218).

TEISSIER DU CROS, L. and E. (1031, p. 1223).

The Jury, in testimony of their admiration of the qualities of the silk exhibited in the French Department, unanimously voted a recommendation of the award of a Council Medal to the CENTRAL SOCIETY OF SERICULTURE OF FRANCE (see page 69).

The Jury desire also to express their estimation of the highly promising qualities of the silk exhibited by the colonists in Algeria; and to specify as deserving Honourable Mention the following exhibitors of raw silk in the French Department:—

M. A. BAHUIT (17, p. 1173).

M. MEGIN (Algeria) (39, p. 1261).

M. G. L. AFOURTIT (749, p. 1216).

M. C. JARNAL (410, p. 1197).

MM. BARRIS BROTHERS (41, p. 1173).

L. DE BARTHELATS (757, p. 1216).

Madame DE NOUVILLE (760, p. 1216.)

MM. V. BONNAL and CO. (429, p. 1199).

M. BONNETON† (771, p. 1270).

MM. CARRUT and ROUX (81, p. 1175).

M. F. CARRUTHE (1136, p. 1232).

MM. CAUQUE and GARION\* (1137, p. 1232).

M. N. CHAMPOURNAU (744, p. 1218).

MM. CHARTRON and SON† (796, p. 1218).

\* These exhibitors' names are inserted in the Award List of Class VIII. W.

† These exhibitors receive Medals in Class III.

- M. P. DARRAS (470, p. 1260).  
 MM. DARVIEU, VALMALE, and Co. (1169, p. 1233).  
 M. V. DELARBE\* (1178, p. 1234).  
 M. A. DELOUZE (1178, p. 1234).  
 M. X. DUMAIN\* (1175, p. 1181).  
 M. DUSSOL (150, p. 1178).  
 MM. EYRIEU and Son\* (831, p. 1220).  
 MM. FABRIQUE-NOURAY, BARNOUM, and Co.\* (832, p. 1220).  
 M. H. FARJON (1217, p. 1236).  
 M. HERMET\* (537, p. 1204).  
 M. LAVERNE and MATHIEU, dit VERGER\* (1298, p. 1239).  
 M. MÉJEAN\* (1353, p. 1241).  
 MM. MOURGUE and BONSQUET (1363, p. 1241).  
 M. J. L. NOGAREDE (937, p. 1225).  
 M. J. PRADIER (1406, p. 1243).  
 M. E. REIDON (1430, p. 1244).  
 M. L. ROECK (1146, p. 1245).  
 M. P. SAMBUC, (1470, p. 1246).  
 M. VERDET and Co. (1519, p. 1246).  
 M. J. VINCENT (1526, p. 1250).

### Spain.

Good examples of Silk, commendable for their length, elasticity, strength, and brilliancy of the thread, are shown in the Spanish Department; amongst which the Jury select the following as deserving the award of the Prize Medal:—

- The AGRICULTURAL BOARD, Valencia (209, p. 1342).  
 MM. LOTREY and Co. (215, pp. 1342, 1343).  
 M. F. MONFORT (202, p. 1342), who exhibits cocoons from the variety of Spanish silkworm called 'Trevolfinho', from that called 'Riacho', and from the Turkey silkworm.

M. RIA and Co. (207, p. 1342).  
 The Jury also award the Prize Medal to the PROVINCE OF MURCIA (199, p. 1342), for the excellence of the specimens of 'Sanza', or silkworm gut.

The Jury have selected for Honourable Mention from the Spanish exhibitors of Raw Silk, T. TRENOR, of Valencia (210, p. 1342); J. CALDERON, of Granada (220, p. 1343); and the specimens exhibited by RODRIGUEZ LEAL (220).

### Belgium.

From the Raw Silks exhibited in Belgium the Jury select for Honourable Mention:—

- A. DE CONINCK (112, p. 1154). C. DE MEYUS (86, p. 1154). A. DE POTTER (111, p. 1154).

### Tuscany.

Among the Italian Silks the first mention is due to those exhibited in Tuscany, which show well the desirable qualities of the cocoons and thread. From these the Jury select for the award of the Prize Medal,—

- G. FRANCOCHINI (56, p. 1295).  
 T. LEFONI (60, p. 1295).  
 N. POIDEBAUD\* (51, p. 1295).  
 P. RAVAGLI (61, p. 1295).  
 SCOTT BROTHERS (49, p. 1294).  
 P. ZAVAGLI (52, p. 1295).

And as deserving Honourable Mention:—

- C. F. CASUCCINI (63, p. 1295).  
 L. DAVITTI (59, p. 1295).  
 L. DELLA KIPA (50, p. 1295).  
 R. LAMBRUCHINI (48, p. 1294).  
 C. G. MORDINI (58, p. 1295).  
 C. PRATOCCI (52, 1295).  
 COUNT G. PIESI (53, p. 1295).

PROP. SAVI (64, p. 1295), for the specimens of raw silk from silkworms fed upon leaves of the Philippine mulberry.

### Switzerland

- \* The specimens of Raw Silk exhibited by T. B. FOULARDI, of Milano (54, p. 1270), are considered by the Jury as deserving of Honourable Mention.

\* These exhibitors' names are inserted in the Award List of Class XIII.—W.

\* These exhibitors receive Medals in Class XIII.

### Sardinia.

In the Department of Sardinia, the Jury have selected as deserving, for their excellent qualities, the Prize Medal, the silks exhibited by,—

CASERIA and Sons (27, p. 1303); H. JACQUET and Co. (26, p. 1303); RIGON and Co.\* (30, p. 1303). And the Jury regard as deserving 'Honourable Mention' the examples shown by:—

- BORZONE, J. (45, p. 1304).  
 MICHAEL BRAVO\* (24, p. 1303).  
 IMPERATORI BROTHERS (38, 1303).  
 SINIGAGLIA BROTHERS (25, p. 1303).

### Austria.

In the Department of Austria are exhibited some fine examples of Italian silks, from which the Jury select for the award of the Prize Medal:—

- G. QUERRINI, Venice (84, p. 1019).  
 SCHEIDLER and Co.,\* of Milan (80, pp. 1011, 1012).  
 VERZA BROTHERS, of Milan (87A, p. 1012).

From Austria Proper the Jury also consider the 'SILK-WORM BREEDING ASSOCIATION OF GRATZ', Styria, as highly deserving the Prize Medal, for the specimens exhibited by them under No. 73, p. 1011.

The exhibitors of raw silk deserving Honourable Mention are:—

- BOZZONI BROTHERS, of Rivar.  
 G. B. MATTIUZZI, of Varvaro, Friuli (77, p. 1011).  
 A. SCOLA, of Upper Austria (72, pp. 1010, 1011).  
 F. SILCHI, of Milan (81, p. 1012).  
 SINIGAGLIA and CARMINATI, of Parma, Friuli (78, p. 1011).  
 G. SILINER and Sons, of Bergamo (87, p. 1012).

### Prussia.

The Jury wish to distinguish by 'Honourable Mention' the specimens of raw, white, and spinning-silk, produced in Berlin, by means of a hanging spinning-lave, on the principle of bee-hives, invented by the exhibitor, A. M. BOLZANI (38, p. 1050), by the use of which no double cocoons can be produced. And also the specimens of silk exhibited by KISZEWSKI (39, p. 1050).

### Russia.

From the examples of silk transmitted from Russia, the Jury select:—

P. RIZA (138, p. 1370), from Tauride, district of Molotschansk, as exhibiting the finest quality of the thread, and as meriting the award of the Prize Medal. And as deserving 'Honourable Mention':

A. REUBON, of Stavropol (139, p. 1370); and M. RAYKO, of Odessa (140, p. 1370).

### Turkey.

The silks exhibited in this Department are, many of them, of a very fine character, exhibiting a good length of thread, with the qualities of fineness, strength, elasticity, and lustre. The Jury select, as meriting the Prize Medal, the following exhibitors:—

- MOUNTAPHA NOUR PACHA, of Broussa (1764, p. 1387).  
 J. PAULAKY, of Broussa (1711, p. 1388).  
 SCOTT or SCHEMLAN, Mount Lebanon (60, p. 1387).  
 THE SCHOOL OF SERICICULTURE AT BROUSSA (1388).

The Jury desire, in same manner, to distinguish the excellent specimens of raw silk and of cocoons exhibited by MIGHIRDITZ DJEZAIBLOU (159, p. 1387), and by MORGUN and of Co., Beyrout (191, p. 1387).

### Bavaria.

A Prize Medal is awarded to—

PELIOWZ, BRENTANO, and Co., of Augsburg (36, p. 1100).

### Sicily.

The specimens of raw silk exhibited by W. JACONE and Co., of Messina, exhibit the best qualities, and merit the award of the Prize Medal.

\* These exhibitors receive Medals in Class XIII, in whose Award List their names appear.

### Sweden.

Among the specimens of raw produce transmitted at a late period of the Exhibition from Sweden, the Jury desire to particularize, as meriting Honourable Mention, the fine examples of raw silk exhibited by Her Majesty the QUEEN OF SWEDEN (1848).

### India.

Very fine examples of silk are shown in the Indian Department, from which the Jury select, as meriting the Prize Medal, the following exhibitors:—

- D. JARDINE, of Calcutta (p. 891).
- C. R. JENNINGS, of Commercially (p. 892).
- MACKENZIE BROTHERS, of Bengal (p. 892).
- W. MCNAB, of Surdah, Bengal (p. 891).
- WATSON, of Surdah, Bengal (p. 891).

The specimens of silks exhibited from Mysore deserve Especial Mention.

The raw silk from Persia exhibited by Mr. THOMSON (8, p. 1426), likewise receives Honourable Mention.

### China.

In the Chinese Department, the quality of the silk developed in the native country of the silkworm is worthily illustrated by the specimens exhibited by YUN-KER, of Shang-hae (p. 1118), to whom the Jury, therefore, adjudge the Prize Medal.

The Jury regard the specimens of silk exhibited in this Department, by Messrs. ASTELL and Co. (p. 1422), Mr. C. J. BRAINE (p. 1421), Mr. HAMMOND (p. 1425), and Mr. LINDSAY (1422), as severally meriting Honourable Mention.

### Mauritius.

In this colony the cultivation of the silkworm has been greatly promoted by the company formed by the exertions of M. E. DUPONT, of Port Louis (2, p. 95), and the Jury award to him the Prize Medal, for the excellent qualities of the white silk which he has transmitted.

Amongst the specimens of raw silk from the Roman States the Jury find worthy of Honourable Mention:—

- D. BERRIETTA (6, p. 1285), and M. BOLGIAN (38).

In those from Malta the Jury award Honourable Mention to

- G. PULIS (4, p. 914).

### England.

The specimens of silk, from silkworms reared on leaves of the white mulberry, at Godalming, Surrey, and exhibited by Mrs. CATHERINE DODGE (32, p. 197\*), possess qualities which, considering the unfavourable conditions of climate, have deserved, in the opinion of the Jury, Honourable Mention.

The Jury regard the raw silk exhibited in the Canadian Department, by Messrs. MACKAY and Co. (144, p. 966), as deserving Honourable Mention.

### FEATHERS AND DOWN.

An instructive and comprehensive collection of feathers and down, in different states of preparation for bed-stuffing, including English goose feathers, Irish goose and mixed feathers, Danzic feathers, Russian goose feathers, and mixed duck feathers, Hudson's Bay goose and duck feathers, Russian down and Greenland eider-down, are exhibited by Messrs. HEAL and Sons (59, p. 199\*), of which the Jury desire to make Honourable Mention.

Messrs. W. and C. NIGHTINGALE (57, p. 199\*) exhibit an illustrative collection of feathers and down, showing the effects of their mode of purifying feathers by steam, without the use of sulphurous gas. Of this collection the Jury desire to testify their approbation by Honourable Mention.

Messrs. BLYTH, HAMILTON, and BLYTH (60, p. 190\*), exhibit excellent examples of purified English white goose feathers and of Irish white feathers, for which also the Jury award Honourable Mention.

In the Russian Department good specimens of white B. jatak bed-feathers, grey feathers, and goose-down are

exhibited by J. LARSHIN (145, p. 1371), of St. Petersburg.

Madame LADIMIRIN, of Tamboff (283, p. 1375), exhibits a fine quality of down from the breast of the goose; together with articles made of goose-down.

A. POROFF, of Moscow (144, p. 1371), also shows down of the first quality.

Each of these exhibitors deserves, in the opinion of the Jury, Honourable Mention.

### B.—FOR DOMESTIC OR ORNAMENTAL PURPOSES; OR FOR THE MANUFACTURE OF IMPLEMENTS.

#### OILS, WAX, &c.

A class of substances was exhibited under the head of 'oils,' which are likely to prove of great commercial importance, as they possess properties differing from the finest vegetable oils, and some of them can, it appears, be supplied in large quantities, and at moderate cost. The Jury, with a view to mark their appreciation of this class, awarded a Prize Medal to R. CLARENCE, Cape of Good Hope (13, p. 950), for oil obtained from sheep's tails, and 'Honourable Mention' to G. DOMINIC (21, p. 1434); T. EMORY (18, p. 1434); F. FRANK (19, p. 1434); and HOLBROOK and STANLEY (208, p. 1450), United States, for oil obtained from lard by pressure at a very low temperature.

Honourable Mention was also awarded to C. A. JETT, Canada (109, p. 965), for oil obtained from porpoises, and which is used largely for lighting purposes; to C. ROMER, Prussia (337, p. 1070), for a sample of oil exhibited by him.

A Medal was awarded to MOSES, SON, and DAVIS, New South Wales (15, p. 990), for tallow.

Some fine white wax was exhibited in the Portuguese Department by M. F. BRETES (620, p. 1514), and by M. L. DE CARVALHO (617, p. 1314); both were awarded Honourable Mention. Honourable Mentions were likewise awarded to M. GRISO, Sarbinia (23, p. 1303), and W. ROYT, Van Diemen's Land (293, p. 998), and E. E. VISSER, Netherlands (17, p. 1143), for the samples of wax exhibited by them.

#### HORNS AND ANTLERS.

Of these productions a great variety of fine and illustrative specimens are exhibited; amongst which the collection in the Indian Department (p. 892) merits the first notice for the number and variety of the examples. There are shown the dense antlers of the *Cervus Aristotelis*, of the 'barn sinha' (*Cervus Duvaucellii*), of the 'Samber' (*Cervus hippelaphus*), of the 'kaher' or barking deer (*Cervus vaginalis*, Boddaert), of the 'axis' (*Cervus maculatus*), of the 'mar' (*Capricornis bubalina*), of the 'hog-deer' (*Cervus porcinus*), of the 'Rusa,' and other species of Indian deer. Horns of the great 'Arnee' buffalo, (*Bos bubalus*), of the 'gour' (*Bos capensis*), of the 'gyl,' and of other kinds of Indian buffalo, ox, and antelope, were also exhibited.

Canada.—A pair of fine moose-horns (*Alces Americana*) are shown in No. 99, and a second pair, No. 237, p. 965, by Mr. J. THOMPSON, of Three Rivers.

From the Cape of Good Hope fine buffalo horns are shown in No. 16, p. 950, by Mr. MEENAR; and rhinoceros horns, in No. 28, p. 950, by Mr. HANNURY.

From Egypt have been transmitted horns of the bull and buffalo, of antelopes, and of the two-horned rhinoceros.

It does not appear that any of the specimens exhibit improvements of size or texture as the consequence of modifications in the food or habits of the species, superinduced to that end by the art of man. The functions of the Jury, in judging between degrees of excellence as the consequence of human ingenuity and skill, find no exercise in regard to the present class of raw materials; and the Jury therefore limit themselves to the above notice of some of the more remarkable collections and specimens of 'horns and antlers.'

## IVORY.

The same considerations necessarily limit the functions of the Jury with regard to the tusks of animals presenting the modification of dental substance to which the term 'ivory' is applied. Fine ivory, distinguished by the descending curved lines on the surfaces of transverse fractures or sections of the tusk, is peculiar to the African and Asiatic elephant, among existing quadrupeds, and the best is obtained from the wild individuals; domestication of the elephant, in India at least, having been usually attended by deterioration of the length and quality of the tusks.

The finest specimens of elephants' tusks are—a pair weighing 326 lbs. of the *Elephas Africana*, obtained from an animal killed near Lake Ngami, in South Africa; each tusk measures 8 feet 6 inches in length, and 22 inches in basal circumference. A single tusk, weighing 110 lbs., from the same locality, is associated with them. These specimens are exhibited by Mr. JOSEPH CAWOOD (p. 952), to whom the Jury award Honourable Mention.

Messrs. FAUNTLEROY and SONS, Potter's Fields, Tooley Street, exhibit an instructive collection of elephants' tusks in No. 135, pp. 205\*, 206\*. The largest of these is from the African elephant, and weighs 139 lbs. Varieties of tusks are also exhibited from the Gold Coast, the Gaboon River, Zanzibar, the Cape of Good Hope, Angola, Alexandria, Ceylon, and the East Indies. The mode of implantation of the tusks is illustrated by the skull of the African elephant. Of the tusks which exhibit a dense texture, but have not the engine-turn markings of true ivory, Messrs. Fauntleroy exhibit those of the 'narwhal,' the 'walrus,' and the 'hippopotamus;' and the Jury regard this instructive collection as deserving Honourable Mention.

Fine tusks of the Ceylon variety of elephant are shown in the collection from that country; and several examples of the continental Asiatic kinds are exhibited in the Indian Department, among which may be noticed some tusks of the Siamese elephants, one of which weighs 106 lbs., and shows a fine white compact kind of ivory.

Messrs. BUCHANAN and LAW (p. 952) exhibit, from the Cape, an elephants' tusk weighing 103 lbs.; and Messrs. HUTTON and SONS (p. 954), show ivory from Dahomy.

## TORTOISE-SHELL.

The substance, so called, consists of certain large horn-like epidermoid plates, which cover, in an imbricated or overlapping manner, the carapace or back-shell of the marine tortoises or turtles (*Chelone*). The species which afford the most valuable of these plates are—the 'Karet' tortoises or imbricated turtles (*Chelone imbricata*, *Chelone caretta*), from which are obtained 5 large plates off the middle of the carapace, and 4 large ones off each side; these plates, 13 in number, are technically called 'blades;' 25 smaller plates are obtained from the margin of the carapace, which are called the 'feet' or 'noses,' in commerce. The other plates, collectively, are called the 'head' of the turtle.

Fine specimens of 'tortoise-shell' have been sent for exhibition from Trinidad, by Lord HAVING (p. 973); of which, as well as of those sent from Labuan by Messrs. HAMMOND and Co. (p. 988), and from Ceylon (p. 938), the Jury desire to make Especial Mention.

## PEARLS.

These precious substances are the result of an excretion in superimposed concentric laminae, of a peculiarly fine and dense nacreous substance, which consists of membrane and carbonate of lime. The finest quality of pearl is produced by the bivalve of the Indian Seas, called 'par excellence' the 'pearl-oyster,' (*Meleagrina margaritifera*), fine specimens of which are exhibited in the Indian and Ceylon collections.

Pearls of an inferior description, formed in a freshwater bivalve (*Unio margaritifera*), are exhibited under No. 15, p. 123, Class I. by JOHN NELLIS, of Omagh, county Tyrone, from specimens obtained from the deepest parts of the River Surule, near Omagh. Similar pearls, also found in the *Unio margaritifera*, from the

river Ythan, Aberdeenshire, are shown under No. 16, p. 122, Class I. by Messrs. OWEN and RAE, of Ellon, Scotland. It is probable that the pearls from this source, collected by the ancient Britons, may have given rise to the statement by Tacitus in his 'Life of Agricola,' of pearls "not very orient, but pale and wan," being among the indigenous products of Great Britain. Pearls, similar to those from the *Unio margaritifera*, are exhibited under No. 41, p. 1352, Sweden and Norway, by TORSTRAUP, from Christiana.

## MOTHER-OF-PEARL, OR NACRE.

In the Indian Collection are shown most of the shells which yield the manufacturer the finest kinds of nacre; these are the *Meleagrina margaritifera*, *Haliotis gigas*, *Haliotis iris*, and a large species of *Turbo*, which shells are known in commerce as flat-shells, ear-shells, green snail-shells, buffalo-shells, Bombay shells. The mother-of-pearl is the internal or nacreous layer of such shells.

Fine specimens of some of these shells, from Singapore and Manilla, especially the great *Meleagrina* and *Haliotis*, are exhibited by Messrs. FAUNTLEROY, under No. 135, pp. 205, 206; and by Mr. BANKS, under No. 287, p. 626, Class XXII. in connexion with the manufacture of mother-of-pearl buttons. As no specimens, however, of this raw material exhibit improved qualities as the result of human skill or ingenuity, the Jury limit themselves to the Honourable Mention of the largest and most instructive collection—which will be found in the Indian Department.

## CAMEO-SHELLS AND CORALS.

Specimens of cameo-shells (*Cassia rufa*), species of *Cypræa*, and of shells used as ornaments by certain natives of India, with the rude but efficient instruments for cutting them, are shown in the Indian Collection.

Shells adapted for cameo-cutting are dense, thick, and consist of three layers of differently-coloured shell-material. In the *Cassia rufa* each layer is composed of many very thin plates—in other words, is "laminated" the lamina being perpendicular to the plane of the main layer: each lamina consists of a series of elongated prismatic cells, adherent by their long sides. The laminae of the outer and inner layers are parallel to the lines of growth, while those of the middle layer are at right angles to them. In the cowries (*Cypræa*) there is an additional layer, which is a duplication of the nacreous layer formed when the animal has attained its full growth.

One of the finest examples of the red coral (*Corallium rubrum*) is exhibited by Messrs. PARAVAGUA and CASSELLA, under No. 84, p. 683, Class XXXIII., in connexion with cameo-work and carving in coral. The Jury desire to award to these exhibitors Honourable Mention for the branch of natural rough coral above referred to.

The Jury desire, also, to make Honourable Mention of the coral exhibited under No. 1, p. 949, MAITLAND MINES, from the Cape of Good Hope; and of the specimens of coral shown by Messrs. IKKEFALLI and SON, under No. 69, p. 1297, Tuscany. Specimens of red coral are exhibited in the collection from Algiers. A fine collection of both corals and madrepores, including the black flexible coral (*Gorgonia*) is shown by R. TUCKER and Co. (Bermuda), for which the Jury award Honourable Mention.

Specimens of cameo-shells, of shells used as ornaments by certain natives of India, with the rude but efficient instruments for cutting the shells, and several kinds of coral and madrepore, are shown in the Indian collection.

## SPONGES.

Of the numerous varieties of the common flexible sponge (*Spongia officinalis*), shown in different departments of the Great Exhibition, the Jury select first, for Honourable Mention, the specimens exhibited in Tunis, by SOLYMAN ESSADY, under the Nos. 73, 74, and 75, p. 1415. They likewise desire to distinguish, in the same manner, the samples of sponges shown by B. PAYLIDES, No. 12, p. 1402, Greece, from the Gulf of Naples; the sponges shown by MM. THIERRE-WIDTMARKER and PUECHER, Saxony, No. 4, p. 1104; and those shown by F. WINKLER, Prussia, No. 31, p. 1049.

Very large and fine specimens of sponges are also shown in the collection transmitted from the Bahamas.

#### SPONGE-PILINE.

The substance so called, of which the patent 'epithems' for medical, surgical, and veterinary purposes are fabricated, is exhibited under a great variety of ingenious and useful forms, especially for applying heated fluids to the body in lieu of poultices and fomentations; and the Jury have pleasure in awarding to the inventor, manufacturer, and exhibitor, M. MARKWICK (114, pp. 203, 204), the Prize Medal.\*

#### GOLDBEATERS' SKIN.

This substance is the peritoneal or serous membrane separated from the intestinal tube of the ox, and sometimes of other animals; it is attenuated by being beaten with a hammer, and subsequently prepared so as to resist putrefaction. The Jury desire to make Honourable Mention of the instructive series\* of this material in various conditions, exhibited in No. 108, p. 203\*, by FREDERICK PUCKRIDGE; and also in No. 104, p. 690, Class XXIII., by E. S. MARSHALL.

#### C.—AS AGENTS IN THE MANUFACTURE OF VARIOUS ARTICLES.

##### GELATINES AND ISINGLASS.

The raw materials chiefly used in manufactures derived from the gelatinous texture of animal bodies, may be divided, as regards their commercial value and application, into two kinds:—

1st. The gelatines and glues, properly so called, derived from the dissolution of certain animal tissues, and especially from the waste residue of parts of animals which have served for food, or for the operations of tanning, or for the fabrication, as from bones, of articles in imitation of ivory, or from the waste particles in the carving of ivory itself.

2nd. The cleansed and dried membranes of different species of fish, more especially of the sturgeon family (*Acipenseridae*), preserving a peculiar texture, on which their value in the refining of fermenting liquors more especially depends; such membranes are called 'isinglass.'

##### GELATINES AND GLUES.

The most remarkable progress in the extraction and preparation of gelatines and glues, from the waste remnants of hides and skins, bones, tendons, ligaments, and other gelatinous tissues, has been made in France, in which country the well-arranged and systematic establishments for the slaughtering of the cattle, sheep, and horses in the large towns, give great facilities for the economical application of all the parts of animal bodies.

##### France.

L. F. GRENET (247, p. 1188).—Among the most beautiful productions of this industry in France are the specimens exhibited under the above number, which have been specially noticed in the Section of the Report on the awards of the Council Medal;—that distinction having been recommended by the Jury to their ingenious inventor.

Many manufacturers in France have risen to great eminence in this line by following the processes of M. GRENET.

H. CASTELLE, of Paris, exhibits (107, p. 1176) a still more varied assortment of the modifications of gelatine, among which are particularly deserving of notice the very large sheets of transparent gelatine, colourless, white, of various well-defined colours, and embossed or stamped with elegant patterns. Taking into consideration the variety and perfection of these modifications of gelatine, the Jury award to M. CASTELLE the Prize Medal.

D'EXPERT BROTHERS (496, p. 1201); V. FITOUX (960, p. 1225); N. LE CLERCQ (1302, p. 1239); J. C. A. ROME (1461, p. 1245); MEYER BROTHERS (1624, p. 1253); BOUASSE, LEAFT, and Co. (774, p. 1217), have exhibited beautiful collections of glues and gelatines similar to the foregoing, and applicable to all the pur-

poses for which a pure, colourless, inodorous gelatine is adapted. MM. COIGNET and SON, of Lyons, fabricate, from bones and various other animal remains, considerable quantities of glues and gelatines, good specimens of which are exhibited, together with other chemical products of animal bodies, in Nos 1153, p. 1233. The Jury regard the above-named exhibitors of gelatines and glues as worthy of Honourable Mention.

MM. KRIS DE DREUZE, of Meurthe (353, p. 1194), and M. FAUSSEMAGNE, of Lyons (1699, p. 1253), merit notice for their excellent gelatines from bones and isinglass for the purpose of dressing various stuffs and cloths.

THE COMPANY OF BOUXWILLER (Bas-Rhin) (376, p. 1195), exhibits gelatine in small plates, much esteemed for various preparations or dressings; it is extracted from the bones from which the same Company obtains phosphorus and phosphates of lime. This Company—MM. ESTIVANT BROTHERS (1214, p. 1235), and HUMBER and Co. (1272, p. 1238)—who exhibit excellent specimens of glues—are severally, in the opinion of the Jury, deserving of Honourable Mention.

##### England.

The greater part of the gelatinous products exhibited by the English manufacturers is prepared from isinglass, and chiefly applied to articles of food. The commercial qualities of isinglass are instructively shown in the collection exhibited under Nos. 117, 118, and 141, p. 204. Some exhibitors, however, show excellent glues and gelatines, obtained from various residues of animal bodies, and destined for manufacturing purposes.

Mr. MULLER (125A, p. 204\*), has exhibited a fine assortment of glues and gelatines, analogous to the products of M. Grenet; but a part of his fine gelatine in threads, for confectionery purposes, appears to have been obtained from isinglass. This is deserving of Honourable Mention.

M. DUTAVILLE (25, p. 204\*), shows a beautiful sample of amber-coloured transparent gelatine in shreds, called 'crystalline,' from its glittering surface; and also good filaments of isinglass for culinary purposes. Messrs. WATT and SON (120, p. 204\*), exhibit fine specimens of glue obtained from the refuse pieces of hides and skins. Mr. JAMES VICKERS\* (117, p. 204\*), exhibits a rich variety of specimens of isinglass in the different raw states in which it is imported, and in all the states of its preparation for the various applications for which it is sold. The variety of colours of the different kinds and parts of isinglass is exemplified in elegant forms and arrangements of this material. Messrs. DAWSON and MORRIS (118, p. 204\*), and Mr. GLASS (141, p. 193\*, Class III.), have exhibited good specimens of isinglass, dried, beaten into layers, and cut into threads, exhibiting care and skill in the latter kinds of preparation. The Jury desire to make Honourable Mention of each of the above exhibitors. The Jury also deem worthy of Honourable Mention the beautiful specimens of refined gelatine, exhibited by Messrs. SWINDORNE (119, p. 204\*). The more opaque filamentary specimens resembling isinglass appear, from microscopic and chemical tests, to be refined gelatine, from which the shining surface has been removed by a process of damping. This is a good material for the purposes of the confectioner, but is not adapted for clarifying white wines and beers, or true isinglass.

##### Canada.

Mr. A. MACFARLANE (124, p. 966) exhibits good specimens of glue of the deep brown semi-transparent kind, adapted for cabinet-work, and deserving Honourable Mention.

##### Zollverein.

Three manufacturers here exhibit specimens of the present class of raw materials. One of these, J. G. LOOSKY, of Cologne (336, p. 1070), shows a fine specimen of an esteemed and long-known article called 'Cologne glue' (*Colle de Cologne*), which was the best kind of glue prior to the recent advance in the manufac-

\* This exhibitor was awarded a Prize Medal in Class III.

ture of gelatine, and which is still highly esteemed by the joiner and cabinet-maker. The Jury deem it deserving of Honourable Mention.

M. A. FRAGENSPAN, of Mühlhausen, Saxony (688, p. 1088), exhibits specimens of gelatines of the Dutch and Givet kinds, of the ordinary qualities.

The samples from Belgium—H. BIHET, of Liege (93, p. 1154), and H. G. HANSOTTE DELMOYE, of Liege (94, p. 1154), consist of glues in thick, reddish, transparent plates, presenting the characters of good 'Givet glue,' and deserving Honourable Mention.

From Portugal have been sent (No. 627) specimens of glues of an inferior quality and putrescent odour. The specimens (Nos. 625 and 626) present qualities of the best productions of a gelatinous nature; but the denomination of 'grenetine,' under which they are exposed, indicates their French origin.

The specimens (No. 7) from Sardinia of glue, in thin plates, betray an inferior quality and putrescent odour.

#### ISINGLASS.

This raw material owes the greater part of its commercial value to its special organization, which permits its separation into extremely delicate fibres, capable of operating, mechanically, in the clarification of white wines and malt liquors. In order to obtain the best isinglass, care must be taken to choose the most suitable membranes of the proper species of fish, and to avoid altering their peculiar tissue in the process of drying and preparing them.

#### Russia.

Under these two relations the products of Russia hold their first rank.

MARIMANOFF and ARMAKOONA (81, p. 1369), display specimens of the best quality of isinglass, consisting of the tissues of the air-bladders of the sturgeon (*Acipenser Huo*), well cleaned, and removed and dried without the texture being affected. The Jury select this exhibitor as deserving Honourable Mention.

No. 116 presents a variety of isinglass obtained from the intestinal membranes in the form of elongated stripes, made into bundles. This substance, like the gelatines from the tendons, bones, and hides of cattle, serves well for different culinary purposes, and for the same uses in manufactures as fine gelatine from other sources.

#### India.

Among the specimens from India there are different kinds of isinglass in the raw state, from species of fishes distinct from those of Europe which commonly afford this substance. The principal of these are from a silurid fish, the *Polynemus plebeius*, the dried air-bladders of which are exhibited by Dr. McCLELLAND (p. 891). (A Prize Medal has been given to this exhibitor in Class III.) They possess the fine fibrous tunic which imparts the clarifying qualities that render isinglass so valuable in the manufacture of white wines and beers; and they are also well adapted for the fabrication of fine gelatines used in manufactures and confectionery.

In the same Collection from India are examples of dried sharks' fins, such as are prepared for culinary purposes for the Chinese market; but this raw material is doubtless applicable to the preparation of gelatine for economical and industrial purposes.

#### FRANCE.

Some excellent examples of this substance obtained from eggs, dried and manufactured, are exhibited in France (1538, p. 1250), by M. H. ALLKON, of Annonay, Ardèche, of whom the Jury desire to make Honourable Mention.

#### ANIMAL CHARCOAL, BONE BLACK, IVORY BLACK.

The Jury have examined and compared many specimens of these substances, exhibited by different nations, and propose to distinguish, by a Prize Medal, the charcoal, exhibited by J. H. M. VIGNETTES, France, (1528, p. 1250), and by Honourable Mention the following:—

MM. RUMELANN and Co. (555, p. 1205), for the specimens of granulated and pulverised animal charcoal, included in their instructive samples of different chemical products.

L. RAUCHER, Jun. (1422, p. 1244), for his samples of animal charcoal.

M. TORDEUX (699, p. 1212), for his examples of bone-black, granulated, pulverised, and of various qualities.

#### Portugal.

J. F. PINTO BASTO (629, p. 1314), for his specimens of animal charcoal, in powder.

#### Netherlands.

P. SMITS (20, p. 1143), for his specimen of animal charcoal.

#### Zollverein.

J. WARCHTER (434, p. 1075), for his granulated and powdered animal charcoal, obtained from the scum of sugar in the process of refining.

#### Mechlenburgh-Schwerin.

M. MEYER (6, p. 1134), for his samples of charcoal.

#### Belgium.

B. SEAGHERS (110, p. 1154), for his animal-black, bone-black, and ivory-black.

E. VERSTRAETEN (108, p. 1154), for his specimens of animal-black.

#### England.

D. CHAN (65, p. 541, Class XVII.), for his bone-black and ivory-black.

### D. - FOR PIGMENTS AND DYES.

#### COCHINEAL AND CARMINE.

The beautiful red dye called 'cochineal' is obtained from the dried body of an insect (*Coccus cacti*), which feeds chiefly on the *Cactus coccinellifer* and the *Cactus Opuntia*. The female insects, which are wingless, are alone collected, and the different degrees of value attached to them depend chiefly on the different methods employed to kill and dry the insects. Analyses of the cochineal have yielded chitine, fatty matter, phosphates of lime and of potash, chloride of potassium and carbonate of lime, and the colouring matter to which the name of 'carminum' or carmine is given. The chief use of cochineal is the dyeing of scarlet: the fine colour which it yields is converted to that tint by means of chloride of tin, called by the dyer 'tin spirits.'

The following are the specimens of cochineal which, in the opinion of the Jury, demand Special and Honourable Mention.

#### England.

J. LAWSON and Co. (66, p. 200\*)—Varieties of cochineal from Honduras, Mexico, Teneriffe, Java, and the West Indies.

I. SADDLER (76A, p. 200\*).

#### Spain.

D. J. B. BERNIGUER (192A, p. 1341).

D. M. GOMEZ ALCAIDE (151, p. 1338).

D. E. MERON (150, p. 1338).

The culture of cochineal in Spain, has extended itself of late years along the sandy and barren coasts of the Mediterranean, and with good success.

Another red dyeing substance, called *Grana hermas*, is obtained in some abundance from the shrubs of the province of Huelva, which is sold at Valencia at eight reals per lb. The GOVERNOR of the PROVINCE of HUELVA (937, p. 1334), has transmitted a specimen of this kermes, of which the Jury desire to make Honourable Mention.

#### Algeria.

M. HARDY (28, p. 1261).—The Jury award Honourable Mention to this exhibitor for his very promising specimens of cochineal from that young colony.

Finally, amongst the animal raw products the Jury desire to select for Honourable Mention the specimens of guano from the Cape of Good Hope, exhibited under No. 37, p. 930, by J. SEARIGHT; No. 50, p. 952, by A. DE PARS, and that from Van Diemen's Land, No. 256, p. 997, by J. MILLIGAN.

RICHARD OWEN, REPORTER.

London, November 1851.

## CLASS V.

REPORT ON MACHINES FOR DIRECT USE, INCLUDING CARRIAGES,  
AND RAILWAY AND NAVAL MECHANISM.

[The figures after the Names (between parentheses), refer to the Exhibitors' Numbers and to the Pages in the  
OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

## Jury.

REV. HENRY MOSLEY, M.A., F.R.S., *Chairman and Reporter*, Education Office, Privy Council; Corresponding Member of the Institute of France, and formerly Professor of Natural Philosophy and Astronomy in King's College, London  
Colonel MÉRIN, *Deputy Chairman*, France; Member of the Institute of France and of the Central Jury, and Director of the Museum of Arts and Sciences  
Chevalier ADAM DE BOURG, Austria; Director of the Imperial Polytechnic Institute, Vice-President of the Society of Arts and Manufactures, &c.  
LUGI CAPPELLITTO, Austria, Mechanical Engineer.  
Professor WILLIAM ENGERTH, Austria  
W. FAIRBAIRN, Manchester; Mechanical Engineer  
JOHN FARNS, 67 Upper Guildford Street, Russell Square; Consulting Engineer.  
JOHN HICK, Bolton-le-Moors; Mechanical Engineer.  
H. MIDDLETON, 4 Cheltenham Place, Lambeth; Mechanical Engineer.  
ROBERT MCCARTY, United States; Machinist.  
ROBERT NAPIER, Glasgow; Mechanical Engineer and Ship Builder  
C. DE ROSSIER-CHESN, Belgium; Vice-President of the Chamber of Commerce of Liege.

## Associates.

EDWARD COWPER, Professor of Manufacturing Art and Machinery, King's College, London  
W. H. HATCHER, 22 Hawley Road, Camden Town, Engineer.

THE machines on which the Jury of Class V. has had to adjudicate are generally of the class called "Prime Movers," being those more directly connected with the development of power than with its application. Where, however, the application of the power to the result to be accomplished is direct and immediate, the mechanical expedients by which it is made were also assigned to the consideration of this Jury. While the application is indirect, being made through a series of mechanical elements intervening between the prime mover and the point where the result is accomplished, such intervening machinery was reserved for the consideration of the Jury of Class VI.

It is obvious that in the consideration of this class of machines, the Jury must be chiefly guided by the principles of mechanics as distinguished from those of mechanism. The machines referred to the Jury were divided by the Commissioners into six classes, as follows:—

V. Machines for direct use, including Carriages, and  
Railway and Naval Mechanism.A. STEAM ENGINES AND BOILERS, WATER AND WIND MILLS,  
AND VARIOUS OTHER PRIME MOVERS.

1. Boilers.
2. Land Engines.
3. Marine Engines.
4. Wind-mills.
5. Water-wheels and Turbines.
6. Water-pressure Engines, as Richenbach's, and Armstrong's.
7. Vacuum Power Engines.
8. Electro-Magnetic Engines, &c. &c.
9. Miscellaneous.

B. SEPARATE PARTS OF MACHINES, SPECIMENS OF WORKMAN-  
SHIP. (See also WATER and GAS-WORKS in Class VII.)

1. Heavy Castings or Forgings in the rough; Castings or Forgings, plain, intricate, or beautiful, in the rough.

2. Specimens of Turning in Metals.
3. Specimens in filing and finished Work in Metals, such as Surfaces, Irregular Figures, &c.
4. Valves, Cocks, Pistons, Governors, &c.

## C. PNEUMATIC MACHINES.

1. Air-pumps
2. Blowing Fans
3. Blast Engines for Furnaces, &c.
4. Miscellaneous

D. HYDRAULIC MACHINES, CRANES, &c., PILE DRIVERS, &c.  
(See also Class VII.)

1. Hydraulic Machines—  
Pumps and Fire Engines  
Water Rams.  
Hydraulic Presses, &c.  
Water Meters, &c.
2. Cranes—  
Any sort of Crane motion and contrivances, Jacks of all sorts. (For Windlasses, Capstans, and Blocks, see Class VIII. E.)
3. Piling Engines—(See also Class VII. A.)  
By hand power, or steam.  
Pile-driving Machines.  
Pile Extractors, &c.

## E.

1. Railway Locomotives—  
Inside Cylinder.  
Outside Cylinder.  
Inside Cylinder Tank.  
Outside Cylinder Tank.  
Models.  
Compressed and Hot Air.  
Hydraulic.
2. Common Road Locomotives.
3. Railway Carriages, Waggon—  
Carriages.  
Trucks and Waggon.  
Carriage Models.  
Waggon Models.

4. Railway Velocipedes.
5. Atmospheric Railway Apparatus.
6. Breaks—  
Full Size.  
Models.
7. Buffers, Couplings, &c.  
Buffers.  
Couplings.  
Wheels, Tires, Axles, Bearings  
Miscellaneous.

## F. RAILWAY MACHINERY AND PERMANENT WORK.

1. Permanent Ways complete.
2. Sleepers.
3. Chairs, &c.
4. Rails.
5. Switches.
6. Turn-tables.
7. Station Arrangements.
8. Signals.
9. Miscellaneous.

## G. WEIGHING, MEASURING, AND REGISTERING MACHINES FOR COMMERCIAL, AND NOT FOR PHILOSOPHICAL PURPOSES.

1. Commercial Weighing Instruments.
2. Instruments of Measures.
3. Registering Instruments, Gauges, Indicators, and Tell-tales.

The total number of these objects exhibited was 537, distributed through the seven subdivisions as follows:

## NUMBERS OF OBJECTS IN THE SUBDIVISIONS OF CLASS V.

| A.  | B. | C. | D.  | E.  | F. | G. |
|-----|----|----|-----|-----|----|----|
| 143 | 40 | 9  | 117 | 112 | 73 | 40 |

The following are the proportions in which they were contributed by different countries:—

| Austria. | Belgium. | China. | Denmark. | Egypt. | England and the Colonies. | France. | Netherlands. | Portugal. | Sardinia. | Turkey. | Tuscany. | United States. | Z. German. |
|----------|----------|--------|----------|--------|---------------------------|---------|--------------|-----------|-----------|---------|----------|----------------|------------|
| 5        | 21       | 2      | 1        | 1      | 424                       | 63      | 6            | 1         | 1         | 1       | 1        | 16             | 4          |

The Jury held its first meeting on the 12th May, when it formed itself into three Sub-Juries, which respectively undertook to examine and report upon the objects included under the several subdivisions.

The number of objects referred to the first Sub-Jury (A, B) was 184, to the second (C, D), 128, and to the third (E, F, G), 224.

The reports of the Sub-Juries were made to the whole Jury, which met twice a-week for that purpose, and the Jury visited and examined collectively all those objects which were considered by the Sub-Juries to claim such further examination, including all those recommended for prizes. Its awards were made on that examination.

No other objects were examined by the Jury, in the English Department, than those placed by the Royal Commissioners in Class V of the Catalogue, except such as were referred to them from other Juries. In the several foreign departments the objects were not classed in the Catalogue. The Jury had, therefore, to select those objects in these foreign departments which, in accordance with the instructions of the Commissioners, appeared to belong to their adjudication.

The number of meetings of the Jury was 18: they were all attended by Colonel Lloyd, special Commissioner, and minutes were kept of their proceedings by that gentleman and by the Secretary.

The Sub-Juries assembled, with few exceptions, daily, until their work was completed.

The final awards were made on the 20th of June; they were confirmed by the Group B, of which the Jury formed part, on the 30th of June, and by the Council of Chairmen on the 14th July.

The following table contains a general statement of the numbers of these awards in the several countries which have contributed to the Exhibition, together with the numbers of Exhibitors, and exhibits in each country, and the proportions which these bear to the Medals awarded.

As, for obvious reasons, the machines, so difficult of transport as those of Class V., sent from foreign countries, could not be expected adequately to represent the mechanical capabilities of those countries in respect to such machines, so the Jury are of opinion that the machines referred to their examination from Great Britain, however numerous and in many respects remarkable, do not, in the aggregate, for reasons which it is unnecessary to specify, fully represent the engineering resources and skill of Great Britain, and that any future exhibition would afford conclusive evidence of this fact.

| Total                   | 1 to 9.6                | 1 to 76.7                  | 1 to 8                   | 1 to 7.3                      |

The contributions to the Exhibition of the following eminent engineers who were members of the Jury, or represented in it by gentlemen connected with their respective firms, were excluded from the competition for Medals.

No. 1542, p. 1250. M. C. ARNOUX, coachmaker, 23, Rue du Mont Parnasse, Paris. Articulated railway carriages. No. 13, p. 212. HICK, B., and Son, Bolton. Steam-engine driving Hibbert and Platt's machinery. Portable forges. Expanding mandrils.

No. 130, p. 1014 (Austria). A Dynamograph, by the CHEVALIER DE BURG. No. 26, p. 244. FAIRBAIRN, W., and Sons, Manchester. Six horse-power steam-engine. No. 417. Wrought iron tubular crane. No. 522. Inside cylinder tank locomotive engine. No. 732. Model of tank locomotive engine.

No. 38, pp. 215-217. See Illustrations, 215, 216. MAUDSLAY, Sons, and Field, London. A 16 horse-power double cylinder direct acting high-pressure engine. Connecting rod for an 800 horse-power marine engine. A case of six models, viz., beam, double cylinder, annular cylinder, horizontal cylinder and steeple engines for shallow river navigation. Model of a gun-metal screw propeller.

The Jury has to acknowledge its obligations to COLONEL MORIN, its Vice-Chairman, for the assistance he was obliging enough to give it in conducting many of the dynamometrical experiments, of which the results are detailed in this Report; to Mr. HATCHER, for the calculations founded upon those experiments, for conducting other dynamometrical experiments, and for the zeal and ability with which he has aided the Jury in every department of its labours; to its able Secretary, Mr. HENRY MAUDSLAY, whose knowledge of the machinery on which the Jury has had to adjudicate, acquired as Chairman of the Metropolitan District Committee, has greatly aided its inquiries; and to its intelligent Assistant-Secretary, Mr. MARTIN. The Jury has, moreover, to thank Mr. HENRYMAN, the Manager of the Machinery Department, for the intelligent co-operation and assistance it has received from him.

To these acknowledgments the Reporter of the Jury has to add his own, to Mr. HENRY MAUDSLAY, Mr. HATCHER, and Mr. MARTIN, who acted severally as the Secretaries of the three Sub-Juries, for the assistance given to him in the compilation of this Report, the details of which, whether contained in the tables prefixed to the several sections, or in the notices of machines to which prizes have been awarded in each section, have been collected chiefly by them.

In reporting on the labours of the Jury, it will be convenient to take the objects referred to its consideration, according to the subdivision of the Commissioners.

## SECTION (A).

The following table (see pp. 170, 171) contains a classification of the objects exhibited under this subdivision, with the number under each class exhibited from each country.

Invention with regard to the steam-engine appears from this table to be specially directed to the economy of space.

The tubular boiler is a contrivance for that end, offering, within the same bulk, a greater surface to the action of the heat on the one side, and of the water on the other, than any other form of boiler. There are eight such, or models of them, in the Exhibition, intended for the land engine.

In marine engines this economy of space has a special value and importance. The direction which invention is taking with a view to this economy is shown in numerous expedients for the direct action of the piston rod upon the crank of the paddle-wheel or of the screw propeller, without the intervention of the beam. There are no less than thirty-four direct-acting engines or models exhibited.

A rotary steam-engine, if one could be contrived whose rubbing surfaces were steam-tight and durable, would effect a remarkable economy of space, and would be better calculated than any other to drive a screw propeller. The increased importance thus given by the use of the screw propeller to the invention of rotary engines is indicated by the exhibition of nine such engines or models.

If, among these, none appears to afford a complete solution of the problem, at any rate there is nothing to discourage further attempts. Nor is this problem the less likely to be solved now that a gain of power is no longer looked for from the use of rotary engines, but only a simpler and more convenient mode of applying it.

Such a gain might indeed result from a freer access of the steam to the piston from a diminution of the friction or the jar of the working parts, or from a more complete expansion; but, thanks to the more general diffusion of information in mechanics, practical men now know, that there is no more possibility of increasing the work of an engine by merely altering the direction of the motion of any of its working parts, than there is of increasing the quantity of water which a reservoir will supply, by varying the pipes which serve to distribute it.

The difficulty of assigning the best form to a solid body which is to receive and apply the resistance of a fluid is indicated by twelve competing forms of paddle-wheels and fifteen different screw propellers.

CLASSIFICATION OF STEAM ENGINES AND BOILERS, showing the Number of each Class exhibited from each Country.

Leads Engines of all sorts.

Land Engines of all sorts.

[illegible]

The advantages to be obtained by working steam *expansively*—long known to men of science—are now generally acknowledged. It is, indeed, obvious that by admitting the steam to the cylinder at a *higher pressure than that of the load*, and cutting it off before the stroke is completed, the piston and the mass it carries with it are driven on with a continually increasing velocity, until by the expansion of the steam—after the closing of the valve by which it is admitted its pressure is reduced to an equality with the load, when the piston does not stop—by reason of the momentum it has acquired—but is carried on, the steam yet further expanding, until the stroke is at length completed and a cylinder-full of steam is discharged, expanded considerably *before the pressure of the load*. Whereas by working without expansion, at what is called full pressure, a cylinder-full of steam is expended at every stroke of the pressure of the load.

The Jury has had to adjudicate on various expedients for thus working engines expansively, called expansion gear.

#### • AWARDS IN SECTION A.

No. 8, p. 211, and Illustration, 212. JOHN PENN and Son, Greenwich. 1. A pair of 12-horse power oscillating cylinder direct-acting engines, for river navigation, of light construction and good workmanship for small vessels. 2. A pair of 30 horse power patent direct-acting engines, called trunk engines, for driving a screw propeller.

In these engines, which are similar to those of H. M. steam-ships "Arrogant" and "Encounter," the piston-rod is widened into a hollow cylinder called the trunk, 14 inches in diameter, projecting through both ends of the steam cylinder (2 ft. 4 in. in diameter), and having the connecting-rod jointed to its centre; the width of the trunk, allowing for its play at every stroke (16 in.) in that position, and the stuffing-boxes serving as guides. A considerable economy of space is thus effected, and some costly parts of the machinery are dispensed with. The circular form of the ordinary piston being by this contrivance converted into that of a circular ring, a greater diameter of the cylinder is required to obtain the same area to receive the pressure of the steam, and a greater periphery has to be kept steam tight. There is also a radiation of the heat of the steam in the cylinder from the internal surface of the trunk, to which the ordinary engine is not liable, and a greater surface externally subject to this radiation.

The ordinary packing of a stuffing-box at one end is, moreover, in this engine, enlarged into that of the large convex surface of the trunk (14 inches in diameter) at both ends; and the difficulty of keeping the packing of these steam-tight, is increased by the lateral strain, to which, serving as guides, they are subjected.

These are practical disadvantages which may, for nautical purposes, be compensated by the economy of space which is effected in this engine. It is from this consideration that the Jury has included it, with the river engine, in the award which it recommends of a Council Medal to the makers.

No. 119, p. 1155 (Belgium). COCKRELL J., Seraing, Liège. 1. A pair of 140-horse power vibrating cylinder engines, for the navigation of the R. Meuse. The framing and paddle-centres, usually of cast-iron, being in these engines made of wrought-iron, the requisite strength is obtained with less weight.

The vibrating cylinders being so placed on opposite sides of the crank that each piston completes its stroke in an inclined position of its cylinder (and, of course, when the stroke of the other piston is incomplete), the same crank-pin is made to serve for both pistons, and a single crank supplies the place of the two at right angles to one another, commonly employed to pass the dead points.

2. An outside cylinder locomotive engine, of good construction and workmanship; with a small donkey-engine attached, for keeping up a constant supply of water to the boiler when the engine is stationary.

3. An oscillating direct-acting three-horse power portable engine and boiler, so combined that the weight of the boiler gives stability to the working parts of the engine fixed to the side of it. The arrangement is

simple; the inside of the boiler may be easily cleaned, and the working parts reached.

4. A small donkey-engine, with its pumps and valve-boxes complete, for a steam-bait, to apply usefully the steam which would otherwise be blown off through the waste-steam pipe, in filling the boilers, pumping the water from the bilge or from the sea to wash the decks or sails, &c.; and in case of need, to extinguish fire. A Council Medal is recommended for this collection of machines.

No. 220, pp. 1184-1186. See Illustrations, pp. 1185, 1186 (France). FROMONT and SON, Chartres. A double turbine, constructed on the system of M. Fontaine Baron. The turbine is a hydraulic machine of frequent use in France but almost unknown in England—which, instead of rotating vertically, as water-wheels usually do, rotates horizontally. When constructed with a careful reference to the principles on which the efficiency of all hydraulic machines depends, the turbine possesses these advantages:—

1. It occupies a small space. 2. Turning very rapidly, it may, when used for grinding flour, be made to communicate the motion directly to the mill-stones. 3. It works under water. 4. It works equally well under small and great falls of water. 5. It yields, when properly constructed, and with the supply of water for which it was constructed, a useful effect of from 68 to 70 per cent. being an efficiency equal to that of any other hydraulic machine. 6. The same wheel may be made to work at very different velocities without materially altering its useful effect. This last property is one of great importance in certain applications, and constitutes an advantage of this machine over most others that have their established rates of working; from which it is not possible to deviate without a proportionate sacrifice of power.

The turbine of M. FONTAINE BARON, to which the Jury recommends the award of the Council Medal, appears, from experiments made on its efficiency, to be one of the most successful of the modifications of that form under which PENNEYRON first introduced this machine in France, in the place of the old horizontal water-wheel.

The following exhibitors were awarded the Prize Medal.—

No. 1, p. 211. WATT, JAMES, and Co., 18 London Street, London, and Soho, Birmingham. A pair of horizontal cylinder direct-acting marine engines, of 700-horse power, for driving the screw propeller.

The two cylinders of each engine are placed opposite to one another athwart the ship, and work, by means of guides and connecting-rods, on the same crank of the shaft which carries the propeller. The cranks of the two engines are fixed at right angles to one another.

No. 1, p. 210, and Illustrations. ATKERSON, CHARLES, H. M. Dockyard, Devonport. Patent expansion gear, by which the variations of the expansion may be registered whilst the engine is working.

No. 49, p. 219. COLLINGS, C., and Co., 65 Bridge Street, Westminster. A new and simple method of reversing the slide of an engine, whereby the direction of its motion may be more easily changed.

No. 39, p. 218. CLAYTON, SHUTTLEWORTH, and Co., Lincoln. A six-horse power oscillating cylinder direct-acting portable steam-engine, of plain and simple construction, having a good arrangement of the slide, and is easily manipulated.

No. 3, p. 210. SMITH, F. P., Greenwich. A complete series of models, illustrating the gradual advance and improvement of the screw propeller; which was proposed and brought into general use by this gentleman.

No. 507, p. 1203 (France). FLAUD, H. P., 37 Rue Jean Goujon, Paris. A high-pressure direct-acting five-horse power steam-engine. The revolving parts are well balanced throughout; whereby the strain upon the bearings,

\* Leçons de Mécanique pratique, par Arthur Morin, vol. ii., pp. 329 and 362. The details of numerous experiments made to determine the efficiency of these machines, will be found in Colonel Morin's work.

due to the centrifugal force, and the consequent wear and tear, and loss of power by friction, are avoided. This precaution, expedient in all engines, is the more required in this, as it is intended to work at high velocities (500 revolutions per minute). The high pressure (75 lbs. per square inch), at which it is proposed to work this engine, is, however, to be deprecated as attended with great risk, and with great loss by reason of the high temperature.

No. 924, p. 1024 (France). MAUZAIZE, J. N., 4 Impasse St. Michel, Chartres (Eure et Loire). A friction clutch, for throwing out of gear a single pair of stones in a flour-mill without stopping the mill. On the spindle which carries the mill-stone is fixed a conical cup, into which a cone, fixed on the corresponding driving-spindle, is pressed by means of a screw, until a sufficient friction is obtained to carry the mill-stone round: the reverse motion of the screw releases it.

No. 967, p. 1226 (France). POUYER, —, Mechanist, Rouen. Apparatus by which any number of prime movers may be connected or disconnected at pleasure, so as to work the same machine. By this simple and ingenious expedient, a water-wheel and a steam-engine may be made conjointly to drive the same machine with regularity, the steam-engine doing only so much work as is necessary to make up for the deficiencies of the water-wheel.

No. 40, p. 218. PORN and SON, Edgeware Road. A five-horse power oscillating cylinder direct-acting steam-engine, of good construction and good workmanship.

No. 105, p. 1013 (Austria). SCHMIDT, H. D., Vienna, engineer. A parabolic governor for a steam engine. The balls and rods for raising the valves are the same as in the ordinary governor, except that the centres of the balls are made to move on the surface of a paraboloid of revolution instead of a sphere. This is effected by means of parabolic arms, fixed on opposite sides of the spindle, on which arms the balls slide, the rods which connect the balls with the valves sliding through them to admit of this motion.

Nos. 46, 203, pp. 218, 219. SIMMONS, C. W., Islington, working model of patent chronometric governor, well-known and approved.

No. 41, p. 218. NASTYRIN, J., Pattistoft, Manchester, a small portable direct-acting steam-engine. The cylinder is fixed, vertical and inverted, the crank being placed beneath it and the piston working downward. The sides of the frame which supports the cylinder serve as guides, and the bearings of the crank shaft and fly-wheel are firmly fixed in the bed plate of the engine; the arrangement is compact and economical, and the workmanship practically good and durable.

No. 25, p. 214. CROSSKILL, W., Beverley. A portable oscillating cylinder direct-acting steam-engine, of simple construction and good workmanship.

No. 12, p. 212. EDWARDS, T., Islington Foundry, Birmingham. Patent five-horse power direct-acting high-pressure steam-engine, of simple construction and good workmanship.

No. 14, p. 212. SIMPSON and SMITH, Trafford Street, Manchester. Short-stroke reciprocating high-pressure engine.

If a solid cylinder be conceived to be fixed eccentrically to an axis, and to be enclosed in a rectangular case, through the sides of which case an aperture is left for the play of the axis of the cylinder, and which is suspended from another axis about which it vibrates; and if the external surface of the cylinder be supposed so to fit the interior of the case into whatever position it may slide as it turns round, that it may divide the case into two chambers, the separation of which is steam-tight; then it is obvious that if there be a vacuum created in one of these chambers, and steam admitted into the other, the end of the case and the side of the cylinder will, in the latter chamber, tend to separate, and, in the former, to come together, which tendency will take effect, both the cylinder and the case being moveable. Instead of the axis of the cylinder being fixed and the case moveable, the axis of the cylinder may be moveable and the case fixed, as in the engine exhibited. The power is then transmitted from the moveable to a fixed axis by a crank. When the cylinder has thus been propelled to the opposite end of the case, completing one-half of a revolution upon

its axis, it may obviously be made to complete the other half by reversing the action of the steam; provided that the dead points can be passed. This may be effected by a fly, or by placing a second cylinder on the same axis, at right angles to the first and, a second case,—either the rotation of the axis to which the cylinder is fixed, or the vibratory motion of the case serve to transmit the motive power. This ingenious contrivance appears to be liable to the same objection as others for the same object, in regard to the difficulty of packing. It has the advantage over them of a more even wear.

No. 16, p. 213. DAVIES, JOSEPH and GEORGE, Albion Foundry, Tipton, Staffordshire. Pair of elliptic revolving steam-engines. Two disc engines drive the same shaft, the discs being moveable with the shaft, and the case fixed. The governor is a hollow ball of metal surrounded by a metallic ring loaded on one side. In the bottom of this ball is a vertical slot, whose plane passes through the centre of gravity. The spindle traverses this slot and is jointed to the sphere at its centre. When it is whirled round by the engine, the centre of gravity of the ball and ring tends to rise by its centrifugal force, which is aided by the tendency of the ring to assume a position in which it may rotate about the least of its two principal axes of rotation. This tendency the slot allows to take effect. As the ball thus alters its position, a lever, whose fulcrum is within the ball acting upon a slide upon the spindle, controls the throttle valve. The whole of this mechanism is masked, and the slot being concealed by a cup, the ball appears to move freely in this, &c., unconnected with the machinery whose motion it regulates. The Prize Medal is awarded for the ingenious contrivance of the governor.

Honourable Mention is made of the following:—

No. 4, p. 210. SCOTTHART, SLAUGHTER, and Co., Bristol. A direct-acting engine for driving a screw propeller, of good workmanship.

No. 21, p. 214. LAYCH and INGLIS. Vertical cylinder direct-acting engine. Commended for compactness and good workmanship.

No. 30, p. 214. HANSON and MAX, Ipswich. A five-horse power steam-engine, on Penn's patent trunk principle.

No. 34, p. 214. BUTTERLEY COMPANY, Alfreton, near Derby. An eight-horse power oscillating steam-engine. Commended for simplicity and good workmanship.

No. 37, p. 215. EVANS, J., and SON. Six-horse power high-pressure oscillating steam-engine. Commended for simplicity of construction and good workmanship.

No. 11, p. 212. HAWTHORN and Co., Leith. High-pressure oscillating engine. Commended for its simple construction and good workmanship.

No. 52b, p. 239, and Illustration. WILSON, E. B., and Co. A donkey-engine. Commended for arrangement and workmanship.

No. 70, p. 220. CONSTABLE, W., Brighton. Model of a compensating fly-wheel of ingenious construction.

No. 714, p. 251. HINITT, JAMES, 22, Vauxhall Row, Vauxhall. Working model of a locomotive-engine and tender. Extremely well made and creditable to the ingenuity and industry of the maker—a workman.

No. 200, p. 225. TRICK, JAMES HENRY, 22, Pall Mall. Patent pneumatic governor for regulating the speed of steam-engines. Experience is said to have shown the usefulness of the invention.

No. 50, p. 219. WATKINS and HILL, Charing Cross, London. Sectional models of steam-engines. Excellent models for educational purposes.

No. 328, Class VI., p. 297. RADCLIFFE, —. Trigger for shutting off steam from locomotives. Commended as a very simple arrangement.

No. 67, p. 220. EVANS, WILLIAM. Working model of a double cylinder engine. The inventor and designer of this model is blind.

No. 5, p. 211. TAPLIN, R., 7, Upper Woodland Terrace, Woolwich. Model of a telescope chimney, for marine boilers. Commended as a good model.

No. 10, Class VI., p. 270. MATHER, W. and C., Salford Iron Works. Spring rings for pistons, of good workmanship.

## AWARDS IN SECTION B.

No. 647, p. 247. THE DERWENT IRON COMPANY, Newcastle-upon-Tyne. 1. Rolled iron plates from 17 to 20 feet long for ship-building purposes and for the sway beams of engines. 2. Rolled keel iron, a railway bar, measuring 66 feet 9 inches in length. A great importance has of late years been given to the manufacture of wrought iron in large masses by the increased scale, which every form of construction of iron is assuming. The limited dimensions of the wrought-iron plates, sway-beams, shafts, bars, &c., with which the engineer has to work, are indeed among the chief obstacles to construction in iron. Although much progress has of late years been made in the scale on which it is wrought, yet these are believed to be among the largest specimens ever produced in their respective departments of manufacture, and the Jury were unanimous in their recommendation of a Council Medal to the makers of them. They regret that this recom-

mendation, not having been adopted by the Council of Chairmen, they have only the Prize Medal to award to them.

No. 543, pp. 241, 242. PATENT SHAFT and AXLE TREE COMPANY, Brunswick Iron Works, Wednesbury. 1. Specimens of iron of their manufacture. 2. Patent railway carriage axles and other axles, with illustrations of their process of manufacture. 3. Patent links for suspension bridges, rolled at a single heat.

To form these axles, plates of iron are placed together like the radii of a circle, and tied with pieces of wire. In this state they are heated to a welding heat and then placed under forge-hammers, which have, together with their anvils, circular cavities of the dimensions of the axle to be formed. The fibrous quality of the iron derived from the plates, which are welded together to form it, thus remains unimpaired in the forging. A Prize Medal has been awarded for these articles.

No. 641, p. 247. COALBROOK DALE COMPANY, Stafford-

shire. Specimens of iron, viz., square, round, flat, half-round, oval bar-iron. Angle, T, and girder iron. Tire iron for wheels. Engine, floor, and foot-plate iron. For which collection of exhibits a Prize Medal is awarded. (Council Medal awarded by Class XXII.)

No. 649, p. 247. MERSEY IRON COMPANY, Liverpool.

Samples of patent rolled iron, principally for ship-building, whereby a saving of workmanship in knees for ships is effected. A Prize Medal awarded.

No. 202, p. 226. ASHBY, JONATHAN, Croydon Common, Surrey. A screw friction clutch. Commended as a good invention, of which Honourable Mention is made.

## AWARDS IN SECTION C.

No. 300, p. 226. LLOYD, G., 70 Great Guildford Street, Southwark, Inventor and Manufacturer of the patent centrifugal disc blowing machine, is awarded a Prize Medal.

The vanes of the blower are curved, and the sides conical. The air enters into a space left for its admission about the axis, and is expelled when the vanes are put rapidly in motion at its periphery, into a case which surrounds it, from which it is conducted by a pipe, and the blast applied by a nozzle. The exhauster differs from the blower in not having an outside case. The air is conducted by a pipe from the space to be exhausted to the central part of the exhauster, and expelled at its periphery. The improvement claimed is in the curving of the vanes and in the conical form of the sides. The action is stated to be noiseless, and the power consumed, less than that in the ordinary blower.

The Jury, being desirous of verifying these statements, directed a series of experiments to be made, of which the results are detailed in the following table (see p. 176). The blower being driven by Messrs. Clayton and Shuttleworth's steam engine, through a band which was passed over the drum of M. Morin's dynamometer, the work expended in driving it was registered by that instrument, with whatever velocity it was driven. The number of revolutions made per minute was measured by a counter, and the blast being received into a closed reservoir, was allowed to escape from it by a rectangular pipe, whose aperture could be varied by a slide. The pressure of the air in the reservoir was measured outside, by means of a bent glass-tube communicating with the interior, and containing water.

The pressure of the air in the reservoir being known, and the dimensions of the aperture by which it escaped,

the velocity and density of the blast could be calculated.\* Hence its *vis viva* was known, half of which represents the work which the blast was capable of doing if all its power could have been applied. The apparatus was constructed under the direction of Mr. Hensman, and the experiments were made and the table calculated by Mr. Hatcher (see page 176).

The blower of Mr. Lloyd was found to work comparatively without noise. It is due to him to state that the apparatus at the command of the Jury did not enable them to drive the fan with that velocity which he alleged to be necessary for obtaining the greatest useful effect.

No. 120, p. 1155 (Belgium). THE MARCINELLE AND COUILLET SNEELING COMPANY. A ventilator for air mines. A. FABRY, inventor. This machine consists of two wheels, having parallel axes, each carrying three vanes of a peculiar form, and made to revolve in opposite directions. These vanes engage and disengage with one another like toothed wheels; and as they separate, create, by their peculiar epicyclical forms, a vacuum about the axes of the wheels, discharging the air into a surrounding case, by their peripheries. The wheels do not drive one another by the contact of their vanes, but by an independent mechanical connexion of their axes.

An economy of power is claimed in the use of this machine, as compared with the ordinary means of ventilation in mines. It has been introduced within the last few years in various mines in Belgium, particularly in those near Charleroi. The Jury have awarded a Prize Medal to the exhibitor.

\* A résumé of the theory of this subject, and of other practical questions to which the attention of scientific men has of late years been directed, will be found in the useful work entitled "Afflu Mémoire des Ingénieurs, par G. T. Richard. Paris, 1848."

## EXPERIMENTS ON BLOWING FANS.

Fan No. 1. Lloyd's Form.—Conical sides; curved vanes. Diameter 30 inches.

| Number of Experiment. | Area of Inlet Opening in Square Inches. | Number of Revolutions made by Fan per Minute. | Velocity of Tips of Vanes in Feet per Second. | Pressure of Air in Air-Chamber. |                  | Area of Opening from Air-Chamber in Square Inches. | Velocity of the Air at Orifices from Air-Chamber in feet per Second. | Horse-power at which Engine driving the Fan worked. | Units of Work given out by Engine per Minute, in pounds raised One Foot high. | Units of Work in effluent stream of Air measured by half its <i>vis viva</i> . | Proportion per Cent. of Work yielded by Fan to that given out by Engine. Useful effect per Cent. |

No. 830, p. 1220 (France). ENFER, E. —, 32, Rue de Malte, Paris. Various blowing machines. M. Enfer's blowing machine is an improvement on the ordinary blacksmith's bellows, giving to it a more steady blast. It is composed of two air-vessels, communicating by two pipes, in one of which a cylindrical bellows is worked, and the other serves as a reservoir. By simple but ingenious contrivances the pressure of the air in the second air-vessel or reservoir is regulated, and the bellows is made to drive air into it, both when it ascends and descends. A Prize Medal is awarded.

In reporting upon the hydraulic machines exhibited, it is impossible to refrain from adverting to the general neglect of those elementary principles of scientific knowledge on which the perfection of such machines always depends, and, in some cases, their whole usefulness in an economical point of view. The Exhibition affords positive evidence of the sacrifice of a large amount of capital, and of much mechanical ingenuity, due simply to the ignorance of certain acknowledged principles of hydraulic science. In adverting to this fact, the Jury cannot but observe that the success with which the principles of mechanical science,† in their application to practical questions, are beginning to be cultivated in France, appears in the superiority of the French hydraulic machines. Thus their water-wheels have attained a perfection which is probably nowhere else to be found in the application of water-power. The total amount of such power derivable from the running waters of France, and applicable to manufacturing purposes, has been largely increased, by expedients of a scientific character.‡ Among the most remarkable of these is the introduction,

now almost universal in France, of the curved float-boards of M. Poncelet in undershot and breast-wheels, and of the turbine of M. Fourneyron. It is not, however, only in the adoption of new forms of water-wheels in France, that the improvement has been apparent, but in the better establishment and more skilful working of the old forms; such as are in use in this country.

Of all such expedients for the economical application of water-power, it is a principle that, as far as it may be possible, the water should be received on the machine, without shock, and that it should leave it without velocity. For that there is power lost by the shock of water is apparent from the fact that the whole power of a fall of water may be absorbed in the reservoir into which it falls, by the shock and commotion of its particles; and it is plain that if the water which works a machine leaves it with any velocity which might have been avoided, then the power which must have been expended in giving it that velocity has been thrown away. It is another condition, founded on the same principle as that of avoiding a shock of the water, that there should be no sudden contractions or expansions of the influent or effluent streams. It is, we repeat, on the scientific application of these principles that all expedients for the economical working of hydraulic machines are founded. We have, however, only to pass through the rooms of the Exhibition assigned to this class of machines to find them almost universally ignored.

The record of this fact is important, as placing in an obvious point of view the necessity of other means than are now afforded for the scientific education of mechanical engineers.

## PUMPS.

Notwithstanding the great antiquity of the pump, and its extensive use, it is one of our worst machines, considered, in a mechanical sense, as a means of producing a given result with the least possible expense of power. Simple as is its construction, it appears from the experiments of M. Morin,\* that the amount of power lost in lifting and forcing pumps (such as fire-engines, &c.), amounts to from 55 to 80 per cent. of the whole. So that of the work (in pounds one foot high) done by the motive power to drive the pump, only 45 per cent. in the best, and 18 per cent. in the worst pumps, is found to be yielded; when the weight of water actually raised in pounds is multiplied by the height to which it is raised in feet; the rest of the work being lost in the passage of the

\* Rapport du Jury Central, sur les produits exposés en 1853, vol. ii., p. 14. Paris, 1853.

\* This is the case with the horizontal water-wheel; without the various scientific expedients adopted in the construction and working of that wheel as the turbine, it could not probably in any case be employed with advantage.

† It is but reasonable to expect that the superiority which the French have confessedly attained in certain branches of industry, by cultivating the arts of design, will eventually appear—through the agency of the Écoles des Arts et Métiers—in the scientific character of their machines.

‡ The whole establishment of a water-wheel partakes of this character: the form and dimensions, for instance, of the sluice and compass—the number, dimensions, and forms of the float-boards—the dimensions of the wheel itself—and the rate of working. It has been abundantly shown, by experiment, that by varying these conditions, the work of the same fall may be varied by from one-half to two-thirds of its whole amount.

water through the pump. This fact cannot be too distinctly stated. There are hydraulic machines which yield, in the water raised, from 75 to 80 per cent. of the work done to raise it, and 60 per cent. is a common proportion; but so imperfect an instrument is the lift and force-pump, that the best yields only 45 per cent., the average not yielding more than 36 per cent. So that if that pump could be so improved as to be no more wasteful of power than a well-made water-wheel, or a turbine, or Mr. Appold's centrifugal pump; then the same power applied to it would raise from a given depth nearly twice the amount of water that it now does. The causes of this loss of power are to be sought—

1st. In the small size and the peculiar construction of the valves.

2nd. In the proportion of the section of the barrel to that of the suction and force pipes.

3rd. In the form of the suction-pipe at the extremity where the water enters it, and of the force-pipe at the extremity where the water is discharged.

4th. In the forms of these pipes where they unite with the barrel.

5th. In the proportion of the length of the barrel to the depth from which the water is raised.

It is impossible to say to what extent the loss of power due to these causes may be removed, without experiments directed expressly to that end; this much is, however, certain, that it would be sensibly diminished by increasing the size of the valves, or by any other expedient which should diminish that sudden variation in the section of the stream which the valves create. That variation, attended as it is by a corresponding sudden variation of the velocity of the stream, involves a loss of power varying as the square of the difference of the two velocities,\* and dependent, therefore, on the ratios of the sections of the suction-pipe and force-pipe to the section of the barrel. From inattention to this arises the second source of loss of power we have enumerated. It is well known that the form of the nozzle by which water is discharged from a force-pump influences largely the amount of the discharge, but it is not equally well known that the form of the extremity of the suction-pipe by which the water enters has an equal effect in facilitating its ingress.†

A similar remark applies to that extremity of each pipe by which it communicates with the barrel, and the neglect of it accounts for a fourth source of the loss of power in pumps. A fifth cause to which attention appears not hitherto to have been directed, is the loss of power due to the communication of an unnecessary velocity to the water raised. Any one who gives a succession of quick strokes to the piston of a common suction-pipe, allowing sufficient time between them for all the water which can find its way into the barrel to enter it, will find the discharge per stroke to be considerably greater than when the piston is raised slowly. The reason of this is obvious; a certain amount of power, and no more, is required to be done on the piston in order to raise enough water from the well to fill the barrel. If more than this is done, the surplus manifests itself under the form of vis viva communicated to the water, by which vis viva, if space be afforded for it to take effect (as in the common suction-

pump by efflux from the spout, or by the raising of the valve in the bucket), more water is brought into the barrel than is due to the volume generated by the piston. Half the vis viva of the water under the piston at the end of the stroke measures this surplus work. If a sufficient pause be allowed, and if the head of water above the piston be not considerable, as in the common suction-pump, the upward rush of the water beneath it at the end of the stroke will lift its valve, and a portion of the surplus work (represented by half the vis viva) will take effect in the elevation of more water into the barrel than would fill the space generated by the piston; and thus is explained the fact of the greater discharge from such pumps when worked by quick strokes with intervening pauses, than when worked slowly. If the head of water above the piston be, however, considerable, as in the force-pump, any vis viva which may remain in the water at the end of the stroke will produce a shock, and a corresponding loss of power. This shock, commonly experienced in the action of force-pumps, is accompanied by a violent and prejudicial action of the valves, especially when they are of metal. When the down-stroke of the piston follows so rapidly on the up-stroke as to meet the ascending stream produced by the preceding stroke, the resistance to its descent is increased, as well as the loss of power due to the commotion of the particles of the fluid it traverses.

It is obvious, therefore, that the proportions of a pump, to be worked by a given motive power, should be such, that the power to be expended at every stroke may just bring the water raised to rest, at the end of each stroke.\*

It is immaterial in what proportions this work is distributed over the stroke, or under what varying degrees of pressure it is generated; provided that the pressure never exceeds that of the atmosphere on the surface of the piston.† If this pressure be exceeded, the piston may separate itself from the water beneath it in the barrel, the pump drawing air; and this is more likely to occur at the commencement than at any other period of the stroke, the motion of the water at that point being necessarily slow.

To communicate a finite velocity to the water at the commencement of the stroke, or while the space described by the piston is still exceedingly small, requires a much greater pressure than afterwards; and, the greater, as the section of the suction-pipe is less, as compared with that of the barrel, and as the lift is greater. Thus at the commencement of the stroke a finite velocity of the piston can only be obtained by an extraordinary effort of the motive power associated with the chance of drawing air and of a shock, if the pressure be suddenly applied. A remedy for some of these evils in the working of a pump has been sought in the application to it of a second air vessel, communicating with the suction-pipe immediately below the barrel, or with the top of the suction-pipe and the bottom of the barrel. The commencement of each stroke is caused by a supply of water from this air-chamber to the space beneath it. The influx of the water into that

\* It is measured by half the vis viva due to the difference of the velocities. This application of a theorem of Carnot, having reference to the impact of inelastic bodies, is due to M. Poncelet. It has been fully confirmed by experiment.

† It appears from the experiments of M. E. Belzoni, that by expanding that extremity of a pipe by which the water enters, into a cone, the diameter of whose wide end is 1·2 times that of the other, the contraction of the vein may be nearly destroyed, the coefficient of the ingress being increased from ·62 to ·967. An analogous result may be produced by expanding the extremity by which the water is discharged. By quitting these experiments, a discharge may be obtained which is greater than that due to the section of the pipe, practically converting the contraction into an expansion of the fluid vein. If the length of the intervening pipe be nearly equal to its diameter, the coefficient of this expansion will be 1·35; if it be the length of sixty times the diameter, it will be 1·17. *Morin, Leçons de Mécanique pratique*, vol. ii., pp. 49, 50.

\* These proportions are determined without difficulty. If  $a$  represent the vertical height of the bottom of the barrel above the surface of the water to be raised,  $b$  the length of the stroke,  $K$  the section of the piston, and  $\mu$  the weight of a cubic unit of water; then  $\mu K b$  represents the weight of the water raised from the well into the barrel per stroke, and  $a + \frac{1}{2}b$  is the height of its centre of gravity above the surface from which it has been raised; therefore  $K\mu b(a + \frac{1}{2}b)$  represents the work done in raising it. Taking then  $U$  to be the work yielded by the motive power per stroke, we have, in order that the whole of this work may be expended in raising the water, and that there may be no vis viva in it when all has been raised,

$$K\mu b(a + \frac{1}{2}b) = U; \text{ whence } b = \sqrt{a^2 + \frac{2U}{\mu K}} - a.$$

† If we conceive the stroke to be completed under a constant pressure, which, with the assistance of the valve-reservoir, is possible, the extreme height to which the water in the barrel will ascend is greater than that at which this pressure would hold it suspended without the closing of the suction valve.

space is aided by the pressure of the condensed air in the air-chamber, and when the stroke is completed, the state of condensation of this air is, by the momentum of the water in the suction-pipe, restored, causing it to rush through the passage by which that pipe communicates with the air-chamber. Thus, by this contrivance, the surplus work, or half the vis viva, which remains in the water of the suction-pipe at the conclusion of each stroke, is stored up in the compressed air of the air-chamber, and helps to begin the next stroke of the piston.

The nature of this action will be best understood from that of the hydraulic ram. The contrivance constitutes, indeed, in some respects, a union of the action of the ram with that of the pump; and, besides accomplishing the object for which it was applied, appears to have the effect of considerably economising the power employed in working pumps.

The suction air-chamber has been added to a common suction-pump, exhibited by Mr. SELF (452, p. 235, in the Agricultural Department, where, being made of glass, its action was readily to be seen. It is also introduced in a class of small pumps, called "fire syringes," exhibited by Mr. BADDLEY (409, p. 227), and Messrs. SHAND and MASON (410, pp. 227, 228). Except in the case of the Canadian engine, it does not, however, appear to have been applied in any of the larger class of engines exhibited. It should probably be constructed of much larger dimensions than have been given to it in either of these engines.

#### AWARDS IN SECTION D.

No. 181 (Canada), p. 968. G. PERRY and BROTHERS, Montreal. A carriage fire-engine to be worked by forty men. Highly commended for the large proportion of the sectional area of the suction-pipe to that of the barrel, the large dimensions of the valves, the application of an air-chamber to the suction-pipe, and the general arrangement. In the experiments made by direction of the Jury, no other engine threw a column of water so high as 17 ft., or discharged so great a body of water per man, or yielded so great an amount of work per man measured by the vis viva of the water passing the nozzle. A Prize Medal is awarded.

No. 1310, p. 1239 (France). LETESTU, 118 Rue du Temple, Paris. 1. A fire-engine without a carriage, to be worked by ten men. 2. A marine fire-engine, to be worked by ten men.

Highly commended for the ingenious, simple, and economical arrangement of the pistons, the large dimensions of the valves, and the large sectional area of the suction and force-pipes, in comparison with the barrel.\*

The piston is a hollow perforated cone of brass, to the interior of which is applied a circular piece of leather, like a filtering paper to a funnel, but having a sector cut out, instead of being folded; the radial edges of the leather overlap, and its periphery projects beyond the edges of the cone, adapting itself to the internal surface of the barrel.

When this piston is to be used for suction, it is fixed to the rod with the base upwards; and when for forcing, with the base downwards. In the return stroke, the water passing through the perforations of the brass cone finds a passage between the loose radial edges of the leather, which it separates.

The valve in the air-vessel is a simple disc of leather, screwed down at its centre on a perforated plate. The Jury have awarded the Prize Medal for these engines.

No. 410, p. 227. SHAND and MASON, 245 Blackfriars Road, London. London Brigade carriage fire-engine, worked by twenty-eight men. Metallic valves; for which a Prize Medal is awarded.

MOSES MERRYWEATHER, 63 Long Acre, London (401, pp. 226, 227, and Illustrations). London Brigade carriage fire-engine, to be worked by thirty men. In compliance with a wish expressed by some of the Exhibitors, the

\* The pumps of Letestu gave a greater useful effect, in proportion to the power expended in driving them, than any others, in the dynamometrical experiments of Colonel Morin at the Paris Exhibition of 1849. This useful effect did not, however, amount to *one-half* the power expended.

merits of the above-mentioned engines were subjected to trial in the presence of the Jury, and the following table contains the results of the trial. The engines were worked by soldiers of Her Majesty's regiment of Grenadier Guards, obligingly placed at the disposal of the Jury by their Colonel. Those who worked upon the different engines appeared of the same average size and strength. Their whole effort was in each trial given to the work, and it was so intense as to be continued with difficulty for three or four minutes. No more certain means of comparison could perhaps have been adopted under the circumstances, but if more time had been allowed for the labours of the Jury, and if arrangements could have been made to drive the pumps by steam-power, and to apply to them the dynamometer of MM. Poncelet and Morin, the relation of the useful effect of each to the power expended in working it could have been determined with a precision not otherwise attainable. (See Table, page 180.)

No. 418, p. 234. A Prize Medal is awarded to S. CHEAVIN, Spalding, for a pump for taking the surface-water only of a well, and at the same time filtering it. The suction-pipe is jointed, so as to allow of one portion of it moving in a vertical plane. The moveable portion is supported by a ball float, so that its open extremity may always be near the surface. To prevent impurities from entering, this extremity is protected by six hollow cones of copper finely perforated, of different degrees of fineness, covering one another.

Honourable Mention is made of the following Exhibitors:—

No. 492, p. 227. WILLIAM SHALDERS. Fountain pump. Its peculiarity lies in the connexion of the bucket with the cylinder by a collar of leather blocked into the shape of a truncated cone, its smaller end being fixed to the bucket, and the larger to the barrel. The play of the piston is limited to the height of this leather cone. The cone is supported by a metal collar of a corresponding conical form, from which it unfolds itself as the bucket plays backwards and forwards. Commended as an ingenious and useful application of a known principle.\*

No. 935, p. 1225 (France). NILLIS, jun., Gravelle, near Havre. A double pump, with large cylinders and six-inch valves, constructed on the same principle as Shalders' pump; mounted upon a carriage to be used in excavations. Commended for convenient arrangement and good workmanship.

No. 424, pp. 232, 233 (Illustrations, p. 233). WARNER, JONES and SONS. Deep well force-pump. Commended for the facility with which the valves can be removed to be repaired, and for good workmanship.

No. 409, p. 227. BADDLEY, WILLIAM, 29 Alfred Street, Islington. A portable farmer's fire-engine, applicable also as an agricultural force-pump. Commended for easy access to the valves, the application of a jet-spreader to the nozzle, and for simplicity and convenience of arrangement.

No. 299, p. 1191. LECLERC, H. EUGENE, Maker, 105 Quai Valmy, Paris. A revolving pump, and various jet d'eau. Commended for ingenuity of combination and arrangement.

#### Centrifugal Pumps.

In these pumps, water admitted at the axis of a hollow wheel, revolved by vanes and made to revolve rapidly, is expelled at its circumference.

The pipe by which the water reaches the axis of the wheel (or the reservoir which feeds it) becomes, under these circumstances, a suction-pipe, and if the reservoir into which the water is received from the periphery of the wheel be closed, and a pipe be carried from it upwards, the latter becomes a force-pipe.

The greatest economy of power in such a pump may be expected to be attained when there is the least possible loss of the vis viva of the water in its access to the wheel, and when there remains the least possible vis viva in it when it leaves it. For if there be any loss of the vis viva of the water in its ingress to the pump which

\* A pump on this principle is described in the *Traité de Mécanique* of Boissier, Paris, 1819. The invention is there ascribed to MM. Denisart et Deville. *Machines Hydrauliques*, p. 52: it is probably, however, more ancient.

TABLE OF THE QUANTITIES OF WATER DELIVERED FROM THE SAME DEPTH AND THROWN INTO THE SAME RESERVOIR IN EQUAL TIMES, BY THE SAME FIRE-ENGINES, EACH WORKED BY AN APPROPRIATE NUMBER OF MEN.

\* No experiment with sand, the suction-pipe being accidentally left clear.

### Comparative Experiments on the Quantities of Water delivered by different Engines.

Experiment 13. Merryweather's small engine, with 10 men; employed to feed the small French engine, also worked by 10 men. The supply just equal to the consumption.

14. The two French engines, each worked by 10 men, employed to feed Merryweather's large engine, worked by 20 men. The two engines supplied in two minutes 30 gallons more than the large engine could throw off.

15. Shand and Mason's large engine, worked by 20 men, feeding Merryweather's large engine, also worked by 20 men. The first engine delivered in three minutes 22 gallons more than the last could throw off.

might have been avoided, it is evident that power must have been expended unnecessarily in producing that vis viva. And in like manner, if any vis viva remain unnecessarily in the water when it leaves the wheel, it is evident that the power by which that vis viva was created might have been saved.

The expedients by which the water may be brought to the wheel with the least loss of vis viva are common to this and to other hydraulic machines; those by which it enters and is delivered from the wheel are peculiar to the centrifugal pump.

If the vanes be straight, it is evident that whatever may be the velocity of the water in the direction of a radius, when it leaves the wheel its velocity in the direction of a tangent will be that of the circumference of the wheel, so that the greater the velocity of the wheel, the greater will be the amount of vis viva remaining in the water when discharged, and the greater the amount of power uselessly expended to create that vis viva.

If, however, the vanes be curved backwards, as regards the motion of the wheel, so as to have nearly the direction of a tangent to the circumference of the wheel at the points where they intersect it, then the velocity due to the centrifugal force of the water carrying it over the surface of the vane in the opposite direction to that in which the wheel is moving, and nearly in the direction of a tangent to the circumference, will—if this velocity of the water over the vane in the one direction be equal to that in which the vane is itself moving in the other—produce a state of absolute rest in the water, and entire exhaustion of vis viva. And in whatever degree the equality of these two motions—of the water in one direction over the vane, and of the vane itself in the opposite direction—is attained, in that same degree will the water be delivered in a state approaching to one of rest. The expedient of curved vanes is adopted in Mr. Appold's pump.

With regard to the admission of water to the wheel, it is obvious that it should pass directly from the suction-pipe into the wheel without the intervention of any reservoir in which the vis viva of the influent stream—communicated in the act of rising through the pipe—may expend itself, and that such space should be allowed at the centre as not to alter the dimensions of the influent stream. It would further seem expedient, by means of properly constructed channels, to divide the water into separate streams, and to give to these divergent streams such curvatures as would facilitate their entrance upon the channels formed by the vanes; as in the turbine.

It is obvious that the tendency of the centrifugal force continually to increase the velocity of the water over the vanes as it recedes from the centre cannot take effect in respect to all the particles of water in the same section, unless the sections of the channels diminish. If they do not, some of the particles of water in each section must be continually retarded, and power be uselessly expended in producing this retardation; whilst the current cannot but suffer from it a disturbance destructive of its vis viva.

This diminution of the sections of the channels might probably best be effected by giving to the sides of the wheel the forms of conical discs; an expedient which is adopted in Mr. Lloyd's blowing-machines, and in Mr. Bessemer's centrifugal pump.

The communication of motion to the water of the reservoir in which the wheel revolves, and into which the water is discharged, should by every practicable expedient be avoided; and for this object the water should be kept as much as possible from the sides of the wheel. This is effected in Mr. Appold's pump, by fixing the wheel between two cheeks which project from opposite sides of the reservoir. The velocity with which the wheel must be driven depends upon the height to which the water is to be raised. Beyond a certain height this velocity is practically unattainable. But long before this limit is reached, it becomes inconsistent with an economical application of the power which drives the pump. It is probably therefore only in comparatively small lifts, where a large quantity of water is to be discharged, that the centrifugal pump will be found useful.

No. 420, p. 232 (England). The Council Medal has been awarded to J. GEORGE APPOLD, 23 Wilson Street,

Finsbury Square, London, for a centrifugal pump,\* of 6 feet in diameter, having curved vanes, separated by a central diaphragm, perpendicular to the axis and intersecting the vanes, so as to form a double wheel; to the two parts of which access is given for the water by central apertures six inches in diameter, on opposite sides of the wheel, whose axis is fixed to the diaphragm.

To determine the useful effect of this pump, a series of experiments were made under the direction of Colonel Morin, the Vice-Chairman of the Jury. The results of these experiments are detailed in the following Table. (See page 182.)

The work of the motive power was determined by the well-known dynamometer, constructed by M. Morin, on a principle proposed by General Poncelet. It is the distinctive feature of this dynamometer that it registers each effort of the motive power with the space through which the machine is driven by that effort, however

\* The centrifugal pump is by no means a new invention. Without entering into further particulars of its history, which appears to date back more than a century, it is sufficient to state that it was used in America as far back as 1830; that one was erected in the Navy Yard, New York, by our colleague, Mr. McCarty, in the year 1838, and that improvements in it were patented in the United States in the following year. The curved form of the vanes was adopted in some of the American pumps.† The true principles of that part of the invention would seem, however, not to have been generally understood; and it is a fact not without interest in the history of the invention, and strikingly illustrative of the importance of other views of the principles of mechanics than are commonly among practical men, that these curved vanes appear to have been discarded for straight ones.‡ In an able memoir by M. Ch. Combes, Member of the Institute of France, entitled, "Sur les Roues à Reaction," read before the Academy of Sciences on the 23rd of July, 1838 (see "Comptes Rendus," vol. vii. 2nd Semestre, 1838, p. 306), the theory of the centrifugal pump is discussed, and its obvious relations to the theory of the centrifugal pump are pointed out. The curved form proper to the vanes is insisted on in this paper, and its theory investigated.

In August, 1838, this gentleman took out a *Brevet d'invention*, entitled, "Pour une machine universelle, à force centrale, propre à déplacer les liquides et les fluides aéroformés," &c., which appears to have been a centrifugal pump; a name which indeed he applied to it in a note addressed to the Academy of Sciences in February 1839. From this period M. Combes appears constantly to have advocated the use of the centrifugal pump, and with this view to have caused a model of such a pump to have been constructed, which still exists in the collection of the "École Nationale des Mines," at Paris. The expediency of giving a curved form to the vanes could not but be apparent to him from those scientific considerations on which his investigations were founded, and it is insisted upon or implied in them all.

In 1843 he published a work entitled, "Recherches théoriques et expérimentales sur les Roues à réaction ou à ayaux," in which, treating principally and principally of the turbine, he nevertheless establishes principles applicable at the same time to the centrifugal pump, and arrives at a formula which is applicable to it by a slight modification of the symbols. This relation and this application he specially points out. This explanation has been considered due to our distinguished colleague, M. Combes. The question of priority, either in the invention of the machine or in the mathematical discussion of it, is one on which it is not the province of the Jury to enter.

\* A model of one of them was exhibited to the Jury, by Mr. Gwyn, having this form of vane.

† The following passage is from the preface of the inventor of a centrifugal pump:—"In attempting to construct a centrifugal pump, a very large number of inventors have exhausted their skill in making arrangements of spiral or curved arms on an axle, or in endowments to find the supposed angle or curve, with the diameter, which the fluid would make in passing off, &c., in utter ignorance of the fact, that in obedience to the law of central forces, the escaping fluid takes the shortest line to reach the circumference; or, in other words, that each particle of matter in a state of rotation, when free to escape, moves directly in the line of the radius, until it reaches the circumference, and thence follows the tangent line until influenced by gravity or some other disturbing force."

variable it may be; and that it does this, not for a single stroke of the engine, or revolution of the wheel by which the machine is driven, but continuously, for a lengthened period. The dynamometer was applied to a drum, a strap from which drove the pump. To ascertain the work yielded by the pump, the water, raised by it from a reservoir beneath the floor on which it stood, to a given height above it, was received into a reservoir on the floor, wherein was an aperture of a rectangular form through which it could flow back into the reservoir, and which could be opened or closed to any extent by a slide. When the pump was set to work, the dimensions of the aperture were so adjusted by means of the slide, that the water remained steadily at the same height in the reservoir. The

quantity of water which escaped by the aperture was then obviously the same with that raised by the pump. The dimensions of the aperture and the depth of the water being known, the quantity of water which escaped could be calculated, and thus the water raised by the pump was known.

To ascertain the influence of the curved form of the vanes on the efficiency of the pump, straight vanes were applied to a wheel of the same size, worked under the same circumstances. The results are stated in the Table.

The pumps of Mr. GWYNNE (140, p. 1441) and Mr. BESSEMER (421, p. 232), on which similar experiments were made, the particulars of which are detailed in the Table, had straight vanes.

#### HYDRAULIC PRESSES.

The Prize Medal was awarded to the two following:—

No. 412, pp. 228-230. The BANK QUAY FOUNDRY COMPANY, Warrington, for a large hydraulic press, used for raising the tubes of the Britannia Bridge. This press, one of the largest ever constructed, has a ram 20 inches in diameter, and a stroke of 6 ft. : it lifted, when raising the Britannia Bridge, a dead weight of 1,144 tons, the cylinder sustaining a pressure of nearly 4 tons (3,809) per square inch. It employed an engine of 15-horse power for about half an hour to drive water enough into the cylinder to complete one lift of the press with this weight, or to raise it 6 feet. The weight to be raised was suspended by chains from the two extremities of a crosshead of cast iron fixed on the top of the ram. To strengthen this crosshead, slabs of wrought iron were shrunk upon the top of it, 29 inches thick. The total weight of the press as exhibited is from 60 to 70 tons.

JACKSON, P. R., Salford Rolling Mills, Manchester, (682, p. 249), sends a model of a powerful hydraulic press, which will lift upwards of 3,000 tons. To form the cylinder of this press, rings of wrought iron are shrunk on a thin surface of cast iron. Thus great strength is obtained with a comparatively small weight of metal.

Honourable Mention is made of BRILLHOUSE, E. T. & Co., Eagle Foundry, Manchester (416, p. 230), for their hydraulic press for packing cotton or other material in bales.

#### WATER METERS.

The labours of the Health of Towns Commission have given fresh importance to the invention of water-meters. To afford an unlimited supply of water it is necessary that some means should be afforded of measuring the quantity each house consumes. If each house were provided with a reservoir, into which the water for its consumption were from time to time received, and from which it was distributed, this would be comparatively easy by means of a meter constructed on the principle of a rain-gauge with a divided chamber and a tumbling shoot. The desideratum is, however, to measure the efflux directly from the pipes, under whatever pressure

the service may be made, and to dispense with the reservoir.

Five different contrivances for this object are exhibited. The Jury has, however, found none so far perfected as to satisfy the conditions of a good meter. In the majority of them the measurement is made by the revolution of a fan, like a screw-propeller, fixed within the pipe, and driven round by the effluent stream. Among other objections to which this principle of construction is liable, is the fact that a considerable leakage may be obtained without giving sufficient motion to drive the fan.

A water-meter, exhibited by DODKIN, BRYAN, & Co. (12, p. 218), is constructed on the well-known principle of the disc steam-engine. Although this is free from the defects which belong to meters constructed on the principle of the revolving fan, it is open to those of insecure packing and unequal wear.

#### CRANES, &c.

The Prize Medal is awarded to the following Exhibitors:—

No. 404, p. 227. FOX, HENDERSON, & Co. Derrick crane. This great crane was used in the construction of the Exhibition building itself, and for placing in it the heavy machines exhibited. When required to remove a great weight at a great distance from the vertical column of the crane, the huge arm or derrick is made to descend by the unwinding of a chain from one of its windlasses, a second windlass, driven by the intervention of a wheel and pinion, from the first, is made to wind up a chain, which, passing over a pulley at the end of the derrick, lifts the weight, thus counteracting the effect on the weight of the descent of the extremity of the derrick, and keeping it always at the same distance above the ground. To produce this compensation accurately, it is necessary to give to one of the windlasses the form of a clock fusee.

No. 44, p. 278. ARMSTRONG, W. G., Newcastle-upon-Tyne. Model hydraulic crane for unshipping coals, and for railway stations, docks, and quays. The pressure of water—accumulated by the action of a steam-engine in a cylindrical reservoir loaded with a heavy weight, which cylinder, like a gasometer, rises as it becomes filled—is made by mechanical expedients, of great ingenuity, to communicate the required motions to the crane.

No. 434, pp. 233, 234. McNICHOLO and VERNON, Liverpool. Working model of a patent steam-travelling crane, for lifting and removing heavy weights in timber-yards, goods depots on railways, &c.

Like the ordinary hand-travelling crane, this machine moves upon a tram-road laid upon longitudinal beams, raised from 15 to 20 feet above the ground. A square shaft runs the entire length of this road, and is connected at one extremity with the engine, which causes it to revolve. This shaft is supported by brackets, which swing on centres; so that each may be readily displaced

fact to the researches of M. Morin at the Conservatoire des Arts et Métiers, who has recorded it in the following words on the original ram of Mongolfier, which is preserved there:—"Belier Hydraulique établi, par John White, first in 1772, à Oulton, Cheshire, pour la service de la Brasserie d'Egerton, et rendu automatique par Joseph Mongolfier en 1796, au moyen d'une seconde soupape." It is due to the manufacturers of the rams on which the experiments were made, to state that the arrangements of the Exhibition Building did not allow of the water being admitted through (what they considered to be) a sufficient length of straight pipe to obtain the greatest useful effect.

by pressure applied in the direction of the length of the shaft. Motion is communicated from this shaft to the machinery of the crane by means of a drum, which slides upon it—carried along by the crane—and which displaces each bracket as it passes it.

No. 76, p. 1146. (Netherlands). K. ENTHOVEN, the Hague, Inventor and Manufacturer. An iron crane for weighing and lifting, constructed on an ingenious principle, and of good proportions and workmanship.

No. 411, p. 228. JAMES and Co., 24 Lundenhall Street, Manufacturers. A patent weighing crane for raising heavy goods, and at the same time obtaining their weight.

No. 406, p. 227. E. N. FONDRAINIER, 38 Barclay Street, Sunderland, Inventor. Patent safety apparatus for preventing loss of life and property, when a rope or chain breaks in the shafts of mines. Besides the expedient of a wedge, acting by its pressure upon a wooden frame to arrest the descent of the cage, as in other contrivances for the same purpose, Mr. Fondrainier's machine adds the security of a grip upon a chain.

No. 627, p. 208 (France). J. M. F. MÉHU, Engineer of the Mines of Anzin, Nord. Model apparatus for the extraction of ores, and for the free and safe ingress and egress of miners to and from the mines. By this contrivance it is proposed to make the same shaft and engine lift the ore and the miners, and work the pumps. A four-sided vertical frame, extending from the bottom to the mouth of the shaft, serves as a guide to a series of square cages, which are lifted through one stage of the frame by each ascending stroke of the beam of the engine, and prevented from descending with the descending stroke by a series of stops, which, swiveling on swivels, are pressed back by the carriages as they pass them, and recover their positions by their weight. A similar expedient gives to the shaft which lifts the cages a hold upon each as it rises, and relaxes it as it descends. The cages are made by an ingenious contrivance to unfold themselves, and to pass from the ascending to the descending frame at the top, and conversely, from the descending to the ascending, at the bottom. (Awarded a Prize Medal in Class I.)

Honourable Mention is made of Mr. DANIEL GREATORREX (415, p. 230), 9 Desborough Terrace, Harrow Road, Paddington, for his model of an improved hoisting machine for raising and lowering goods, which can be worked by hand or by steam. The person ascending or descending with the machine can stop it at any point of the ascent or descent.

#### JACKS.

No. 509, p. 237. The Jury award a Prize Medal to GEORGE ENGLAND and Co., Hatcham Iron Works, New Cross, for their traversing screw-jack, useful for railway purposes, and commended for ingenuity of contrivance, and economy of material and space.

No. 490, pp. 236, 237 (Illustration, 237). Also to S. THORSTON and SONS, Birmingham, for their hydraulic lifting-jack, constructed on the principle of the hydraulic press.

#### VALVES.

No. 201, pp. 225, 226. A Prize Medal is awarded for R. HOSKING's triple-beat valve for large pumps, which affords three passages for the water. They are annular and concentric, and, by an adjustment of the weight of the load on each to the surface it offers to the pressure of the water, are made to open and close in succession, thereby diminishing the first effort of the lift of the piston (due to the inertia of the water) and the blow on its descent.

#### COCKS.

Honourable Mention is made of the following:—

No. 476, p. 235. Major ROBERT LITTLE, Woolwich Common, Inventor, for an improved water-cock for connecting pipes without breaking joints. The plug of this cock may be removed to be re-ground, without undressing the pipes.

No. 1608, p. 1254 (France). — FRÉAULT, Brass-founder, Orleans. Hermetic tap. A cock closed or opened by means of a coarse screw acting upon a valve. A good and simple contrivance, not likely to get out of order.

The introduction of curves in railways, unless their radii be very great, has hitherto been considered unwise, and the cost of the construction of railways is, under certain circumstances, greatly increased by this consideration. To give to a train the power, under certain circumstances, itself to change that rectilinear motion to which by the first law of motion it tends, into a motion which shall cause it to follow any curvature, it may be convenient to give to the line, would be to afford new facilities for the construction of railways.

Our colleague, M. ARNOUX, who, as a member of the Sub-Jury on Carriages, was placed out of the number of competitors for medals,\* has attempted the solution of this problem on the railway from Paris to Soaux, and a working model of one of his trains is exhibited in the French Department. On this railway there is a zigzag, the radii of whose curves vary from 165 to 200 feet.

\* As the labours of the Sub-Jury for carriages were conducted independently of the principal Jury, the exclusion

which is said to have been traversed without accident by the trains of M. Arnoux daily, at a speed of from sixteen to eighteen miles an hour, since the month of June 1846.\*

Various models of atmospheric railway apparatus are exhibited; none of which probably will remove that unfavourable impression to this principle of locomotion which recent experiments on a large scale have created.

The construction of railway carriages admits of great improvement, a fact to which the attention of inventors is obviously directed. In the construction of railway waggons, the use of corrugated iron has been introduced; and cast steel for the construction of railway springs appears to be coming into more extended use. Several beautiful specimens of this manufacture from the Continent, as well as from Great Britain, have been exhibited.

To maintain a great speed, the first requisite in a locomotive engine is great evaporating power, and to obtain this there must be a large surface of metal exposed to the action of the heat on the one side, and of the water on the other. This is obtained by Mr. Stephenson's admirable expedient of a series of tubes which traverse the boiler, conveying the heated air from the furnace to the chimney; by which expedient the absorption of the heat from the air, heated by the fire, into the water, is made to extend over a greater surface than by any other.

#### AWARDS IN SECTION E.

No. 512, p. 238. See Illustrations, p. 234. In the engine called the "Liverpool," patented by Mr. T. R. CRAMPTON, to which the Jury recommends the award of the Council Medal, a heated surface of no less than 2,136 square feet is obtained by means of the tubes, besides the surface exposed to the direct action of the heat in the furnace, which measures 154 square feet. The evaporation resulting from this vast amount of heated surface is stated to yield a steam-power equivalent to that of 1,140 horses.

It is a second condition of great speed in locomotive engines, that the piston should make the fewest possible number of strokes whilst the engine traverses a given space; for which purpose the driving-wheels must be the largest possible. By bringing these from the position they have been accustomed to occupy (near the middle of the boiler) to the foot-board of the furnace, Mr. Crampton has succeeded in giving to the driving-wheels of his engine, the "Liverpool," a diameter of 8 feet.

It is a further advantage in the use of large driving-wheels, that for a given velocity of the engine, they diminish the angular velocity of the wheel, thus diminishing the tendency of the wheel to jump, by reason of its centrifugal force when the crank is not truly balanced,† a tendency which, before the attention of engineers was called to the necessity of balancing the crank, was fruitful in accidents. The same expedient by which Mr. Crampton obtains space for larger driving-wheels, enables him to place the boiler lower, and thus—giving a lower position to the centre of gravity of his locomotive—to increase its stability.

The Jury award Prize Medals to the following:—

No. 509, p. 238. GEORGE ENGLAND and Co., Hatching Iron Works, New Cross. Improved locomotive engine for railways of light traffic, weighing, with coke and water, ten tons. The centre of gravity is low; and a good mode

of M. Arnoux from competition for the prize awarded by the Jury of Class V. is made rather according to the letter than the spirit of our instructions.

\* A pair of guide-wheels placed at an inclination of 45 degrees to the vertical on the first carriage of the train, and a similar pair on the last, compel these to take and to keep the curved line of the rail. The wheels of the intermediate carriages are not, as in other railway-carriages, fixed, but loose upon their axles. The axles turn on central pivots, and each axle is made to take the proper position for turning the curve, by a pole which grasps it by two arms on opposite sides of the pivot, and slides upon it laterally, and which is fixed to the next carriage in the train, or to the axle of the next pair of wheels in the same carriage.

† Or from the momentum of the connecting rod, &c., as at every revolution it ascends.

has been adopted of heating the water before it is pumped into the boiler. The driving-wheels of engines so light as this, require to be very truly balanced, or their weight should be very small in comparison with the engine, that they may travel with safety. The award is made for ingenious arrangement and good workmanship.

No. 510, p. 237. W. BRIDGES ADAMS, 1 Adam Street, Adelphi, London. 1. A light locomotive engine coupled to a four-wheeled carriage which supports the end of the engine in case of accident. The engine carries water beneath the floor, and has a sledge break. 2. An eight-wheeled double railway-carriage for first and second-class passengers.

The award is made for combination and arrangement in the locomotive, for the break, which is well executed, and for good proportions and workmanship in the carriage.

No. 506. The GREAT WESTERN RAILWAY COMPANY. Locomotive engine and tender, constructed at the Company's Works at Swindon. One of the ordinary class of engines, manufactured by this Company for passenger traffic since 1847. It is capable of taking a passenger-train, of 120 tons, at an average speed of 60 miles per hour, upon easy gradients. The evaporation of the boiler, when in full work, is equal to 1,000-horse power—the effective power, as measured by a dynamometer, is said to be equal to 743-horse power. The weight of the engine, empty, is 31 tons; coke and water, 4 tons—engine in working order, 35 tons. Tender empty, 9 tons; water, 1,600 gallons, 7 tons 3 cwt.; coke, 1 ton 10 cwt.: total, 17 tons 13 cwt.

The heating surfaces are, fire-box, 156 feet; 305 tubes, 1,759 feet.—Diameter of cylinder, 18 inches; length of stroke, 24 inches; diameter of driving-wheel, 8 feet; maximum pressure of steam, 120 lbs. The actual consumption of fuel in practice, with an average load of 90 tons, and speed of 29 miles, including stoppages (ordinary mail train), has averaged 20·8 lbs. of coke per mile. The award is made for good proportion of parts and superior workmanship.

No. 536, p. 240, and Illustrations, p. 241. R. and W. HAWTHORN, Newcastle-upon-Tyne. First-class passenger locomotive engine. The award is made for a good arrangement of parts, and for an improved link motion.

No. 534, p. 240, and Illustration, p. 1078. KITSON, THOMPSON, and HEWITSON, Leeds. A locomotive tank engine. The award is made for good workmanship.

No. 473 (Prussia). PIEPENSTOCK and Co., Hoerde, near Dortmund, Inventors and Manufacturers. Disc wheel and hollow axle for railways. The wheel consists of a single disc of wrought iron, fitted accurately to the axle and the tire by turning. On the end of the axle and in the inside of the tire, flanges are formed, and the disc being dropped into its place, as the lid of a tin box would be dropped into its rim, is then secured to these two flanges with rivets parallel with the axle. Hence there is no tendency to draw or loosen the rivets, nor are they exposed to any wear or injury when the wheel is revolving. The axle being made tubular, has its stiffness considerably increased, without any corresponding increase of weight. The whole presents an arrangement in which great strength and firmness are obtained without additional expenditure of material.

No. 555, p. 242. J. SPENCER and Son, Newcastle-upon-Tyne. Baillie's patent volute springs. These springs are made of a long plate of steel coiled spirally round a centre, so as to present an outline somewhat like the fusee of a watch. The base being supported, any force applied at the summit tends to force this inwards, and to bring the spring into the form of a flat coil. Several applications of these to the purposes of bearing-springs, buffer-springs, and draw-bar springs are shown.

No. 636, p. 246, and Illustrations. G. R. THORNEY-CROFT and Co., Wolverhampton, Inventors and Manufacturers. Specimens of Brigg's patent compound axle, tire, and rails. The distinguishing principle of the construction of these parts is the forming them of two different characters of iron adapted respectively to the kind of deterioration to which each part is liable, and the strain to which it is subjected. Thus, in the wheel tire, the centre of the

breadth and the inside of the flange are formed of a hard iron fitted to resist the greater wear of these parts against the rail, while a softer and more tenacious iron is used to make those edges of the tire which are exposed to no wear. The great tenacity of this softer iron supplies the strength required in the tire. Similarly the upper surface of the rail is formed of a hard iron, which will not wear away, and which gives strength to the rail by its resistance to the compression to which its upper surface is subjected, while the lower flange is constructed of a tough and tenacious metal fitted to resist the extension produced on those parts of the rail. The railway axles are, in like manner, formed by welding up a tough metal round a central hard core. The two metals are welded together in the course of the manufacture, so as to render the combination of the different qualities of iron perfect.

No. 637, p. 246. GEORGE WORSDELL and Co., Warrington, Manufacturers. Railway axle and railway wheel-tire, forge-hammered. The iron is carefully faggoted and welded up, and the excellence of the work is indicated by the tenacity and strength of the completed axle. The specimen exhibited, which has been bent cold under a pressure of 84 tons, offers a good sample of the result of the process, and is commended as an excellent specimen of manufacture.

No. 646, p. 247. BEECROFT, BUTLER, and Co., Kirkstall Forge, Leeds, Manufacturers. Specimens of railway wheels and axles. Messrs. Beecroft exhibit, among others, a form of wheel peculiarly adapted for express trains, in which lightness should be combined with great strength. These wheels are constructed entirely of wrought iron, the boss and spokes (single and double) being forged in one piece. The tires are then shrunk on and riveted as usual. Their wrought-iron disc wheel displays a mode of so dovetailing the disc to the interior of the tires as to obviate the necessity of rivets. These wheels have also wrought-iron bosses. They are commended for judicious combination and good workmanship.

No. 682, p. 249. P. R. JACKSON, Salford Rolling-mills, Manchester, Manufacturer. Locomotive and carriage tires. The carriage tires exhibited by Messrs. Jackson finished. The exhibit presents a valuable feature in the steeled tires, in which the outer and wearing surface is formed of a thin plate of steel welded (by a process said to be peculiar to the manufacturers) to the iron. By this application it is anticipated that the tendency of the tires to become grooved will be diminished, and their durability be proportionably increased.

No. 640, pp. 246, 247. RANSOMES and MAY, Ipswich. Water-crauc, patent compressed treenails, and wedges for railways.

No. 507, p. 237. J. LEE, Long Acre, Inventor and Patentee. Carriage break. A good example of what has been termed the sledge break. It is analogous to the drag or shoe on common roads. Instead of the resistance necessary to stop the train being created by the pressure of the break against the periphery of the wheel, an iron shoe or sledge is pressed down before the wheel upon the rail, and the wheel mounts the sloping surface of this sledge, which then slides along the rail until the resistance absorbs the vis viva of the train, and brings it to rest. The resistance created by this break being very great, it should not be applied to all the carriages of a train at once. With this precaution it is commended as a useful contrivance.

No. 590, p. 239. C. C. WILLIAMS, Glashouse Yard, Goswell Street. A railway carriage, constructed of Moulmein teak, varnished. This carriage is strong, convenient, and neatly executed; in the substitution of varnish for paint there is an economy, and the carriage may thereby be the more quickly repaired.

No. 592, pp. 239, 240, and Illustrations, pp. 239, 240. HENRY H. HENSON, Pinner, near Watford. Patent covered waggon for the conveyance of merchandise by railway; fire-proof when closed, and so arranged that the side or roof may be opened for loading or unloading. The award is made for the combination of corrugated iron and wood in its construction.

No. 599, p. 240. J. E. MCCONNELL, Wolverton. Railway-passenger carriage. This award is made for an ex-

cellent adaptation of corrugated iron to the construction of railway carriages, and for superior workmanship.

No. 541, pp. 240, 241. JOHN COOPE HADDAN, 29 Bloomsbury Square. Patent railway carriage. Rewarded for the application of papier maché to the construction of railway carriages.

Honourable Mention is made of—

No. 642, p. 247. M. PERCIVAL PARSONS, 6 Duke Street, Adelphi, Patentee and Designer. Among the various exhibits of Mr. Parsons, Normanville's patent axle-box deserves notice. The bearing is entirely enclosed in a cast-iron box, which keeps the axle free from dust or sand, while it preserves the grease, which would otherwise fall on the road and be wasted. This box is cast in one piece, and around the axle is fixed a collar of stiff leather, so as to form a close joint, and prevent the ingress of dirt. As an improvement in the details of the railway system this well deserves attention.

No. 346, p. 969. PIERRE RODIER, Nova Scotia. Working model of a locomotive engine, made by the exhibitor, a boy 14 years old. A paper accompanying this exhibit certifies the boy to have received no aid, either in drawings or workmanship, which display ability and deserve encouragement.

No. 231, p. 1451 (United States). L. C. HIGGINBOTHAM, Vernon, New York. Miniature model of a locomotive engine; made by a boy who lived by the side of a railway. The passing of the trains was the only information within his reach. A remarkable fact, to which the Jury would draw attention as a proof of the youth's singular powers of observation.

## SECTION (F).

AWARDS IN SECTION F.—(See Table, page 188.)

No. 618, pp. 244, 245, and Illustrations (England). The Council Medal is awarded to T. DUNN, Windsor Bridge, near Manchester, for a traversing frame to remove carriages from one line of rail to another.

A strong frame supported on wheels, which are covered by its sides, travels on a railway at right angles to the lines, from one to the other of which the carriages are to be transferred. The level of the upper surface of the transverse rail is a little above that of the principal lines, so that the latter are cleared by the flanges of the wheels of the frame, which therefore freely traverses them. The transverse line is broken where it crosses the principal lines, space being left for the trains to pass. To receive the carriage, a rail is placed like a shelf or ledge at the bottom of the sides of the frame, so as just to clear the surface of the permanent rails; and to raise the carriage upon this shelf a switch is provided, which, turning upon a hinge, may be brought, when the frame is properly placed, into the direction of the principal line. The upper surface of this switch forms an inclined plane, up which the carriage may be raised until its wheels rest upon the shelf. The frame, with its burden, is then pushed sideways along the transverse rail, to the rail to which the carriage is to be transferred, and the switch supplies an inclined plane by which the carriage descends. This traversing frame, supplying (for many purposes) the use of the turn-table, is commended as a useful invention, affording increased facilities for railway traffic.

The Prize Medal is awarded to the following exhibitors:—

No. 602, p. 242. W. H. BARLOW, Midland Railway, Derby, Inventor. Wrought-iron permanent way for railways. The rail in Mr. Barlow's invention is made to form its own contiguous bearing. In section the rail somewhat resembles an inverted V ( $\Delta$ ), with the ends considerably turned outwards. This portion forms the surface by which the rail bears upon the ballasting, the apex of the V being formed with flanges in the ordinary form of rails; and the rail therefore beds throughout on the ballast. It can be very easily packed up and adjusted when out of place, and all the fittings of sleepers, chains, and keys are done away with, nothing being required besides the rails themselves, except a cross or tie-rod at the joints to hold them at the proper distances asunder, so as to keep the gauge of the line. This rail has been tried on the Midland line, and the results, as shown by the diminished

oscillation and vibration of the trains in passing, and the smaller number of hands required to keep this portion of the line in order, are said to be satisfactory.

No. 638, p. 246. **EBBW VALE COMPANY**, 83 Upper Thames Street, London, and **Abergavenny**, Manufacturers. Sections of railway bars of all the forms used in railways. The Prize Medal is awarded to this exhibit in consideration of the facilities it affords for the comparison and study of the different forms of section, which have been devised for giving strength and durability to railway bars.

No. 645, p. 247. **THE CWM AVON IRON COMPANY**. Railway bars, 70 feet in length. The award is made for skilful workmanship.

No. 643, p. 247. **W. BAINES**, Birmingham, Inventor. An improved railway switch, in which the tongue is formed to pass under the upper flange of the fixed rail, by which expedient the point is prevented from rising, and the carriage is made to pass more easily upon the new line. The switch is so formed as to have a broad base for its bearing on the chairs, and it is made so much deeper than the main or fixed rail, that the lower flange of the switch passes under the lower flange of the fixed rail. Two advantages result from this. The flange of the switch keeps the tongue, when closed, from rising, and any stones or dirt which may fall between the switch and rail are swept, as it closes not against the main rail, but under it; thus closing without risk of impediment from dirt or rubbish. The bearings of the switch are also placed a little aside of the bearings of the rail, in order that any stones lying on them may in the same way be swept clear off, and not be caught, so as to prevent the proper closing of the point.

No. 600, p. 243. **CHARLES YOUNG and Co.**, Inventors and Manufacturers. "Simultaneous-acting level-crossing gates for railways." Serious accidents have arisen from the inability of the policemen in charge of level-crossings on railways to open in time all four gates to give passage to an approaching train. Messrs. Young's gates are hung

on posts so set at the four angles of a square or a rhombus, that they close either across the line, and leave the road clear, or close the road, and shut off all approach to the line. By a very simple and obvious connexion beneath the ground between the heels of the several gates by means of iron rods, the motion of any one is accompanied by the corresponding motion of the other three divisions. The policeman has not, therefore, to open and close each of the four in succession, but by simply acting on one, he produces simultaneously the required movement in all. The advantages arising from this arrangement, which is available either for straight or oblique crossings, are obvious, while cost of construction and maintenance is increased only in a small proportion.

No. 552, p. 242. **C. DE BENOÛT**, 9 Dowgate Hill, Inventor and Manufacturer. Patent station buffer. Mr. De Benquet has aimed at producing a station buffer, which should offer to a train impinging upon it a gradually increasing resistance through a long space, thereby absorbing the vis viva of the train gradually, and without shock of the carriages upon one another; and he has sought to do this without the aid of a spring, the recoil of which, when powerfully compressed, might be attended with danger. In his station buffer the train impinges on the end of a long stout beam of wood, slightly tapering from one end to the other. This beam has its smaller end fitted to enter a strong iron box or case. The force necessary to drive this taper beam into the case continually increases as the larger end approaches the case, or as the wood must be more and more compressed to enter the case. At the same time the beam, when driven in to any point by the impact of a train, remains fixed there, having no tendency to fly out or return to its first position. All the injury which may be produced by the recoil of a powerfully-compressed spring is thus avoided, while on the removal of the carriage the iron case is easily unscrewed, and the beam of wood loosened and drawn out to assume its ordinary position.

Among the instruments exhibited in this Section are some dynamometrical machines but little known in this country, but which have been applied in France, with great success, to determine the most favourable conditions for the construction and working of machines, with respect to the economy of power. The machines heretofore used for this purpose have been the steam-indicator of Watt and the friction-break of Prony. The former serves to determine the work done by the steam upon the piston of a steam-engine during any single stroke; and the other, being applied to a driving-shaft when all other work is thrown off it, serves to measure the work by which that shaft is driven, from whatever source it may be derived. It is the object of these dynamometrical instruments to determine the work transmitted to the whole or any part of a machine, not for a single stroke only of a piston, but continuously, through any given period; and to do this without absorbing—as the friction-break does—the whole work to be measured, but whilst the machine is performing its customary work. The amount of work necessary to yield given useful results is thus determined, independently of the influence of any other parts of the machine than those which operate directly on the result.

Every such admeasurement is a manufacturing constant of great value, capable of being employed to determine the cost of production under other and widely different circumstances. Such constants as have yet been thus determined, science owes chiefly to the labours of French engineers.\* These dynamometers have been used not only to determine the power transmitted by machinery from steam-engines and water-wheels, but to manual labour, as applied to the working of pumps and driving machinery by cranks, and to the traction of horses. Every effort of a team of horses through successive days of labour, and journeys as long as that from Amiens, Nancy, and Le Mans, to and from Paris, has thus been measured and recorded, and the work expended on such efforts estimated, aggregated by the machine, and registered in numbers.

The invention of these machines is due to General Poncelet. They were constructed under the direction of Colonel Morin.

The following are the dynamometers exhibited:—

1. The "Dynamometre de rotation," for determining the work transmitted by a revolving shaft.
2. A dynamometer for determining the manual labour of driving the handle of a pump or a crank.
3. A dynamometer for registering the work of the steam on the piston of an engine through any number of strokes. Constructed on the principle of the constant indicator, made in the year 1841 for the British Association of Science, and described in their Report for that year.

It will be sufficient to describe the rotation dynamometer,

\* They have been collected by Colonel Morin in his "Aide Mémoire de Mécanique Pratique." Fifth edition, 1849, Mathias, Paris.

† It is not easy to make this description clear without a drawing. For a more intelligible explanation, the reader is

referred to the "Leçons de Mécanique Pratique," of M. Morin.

meter, which is that used by the Jury in its experiments on the centrifugal pumps.

Upon an axis, having cast-iron supports, capable of being fixed by screws upon the floor, are placed two pulleys, which we will call A and B, the one, A, is fixed on the axis; the other, B, is movable upon it between limits hereafter to be specified. Let it now be supposed that the machine, the power employed in driving which is to be measured, is worked by means of a strap passing over two drums, one of which is upon a shaft connected with the engine, or other motive power, which we will call the driving-shaft. Let this strap be removed, and the dynamometer being conveniently placed and screwed firmly to the floor, let a strap from the drum on the driving-shaft be passed over the drum, A, and one from the drum on the machine over B; then it is plain that if B were fixed to the axis as A is, the strap passing over B would transmit the motion of the driving-shaft on to the machinery; so that the latter would be driven as it was before, except that the work would now be transmitted through the dynamometer, which before it was not. To cause the axis to carry the drum B round with it, a spring, fixed in the axis, passes between knife edges, fixed near the circumferences of the wheel B. This spring being carried round by the axis, and pressing on one of the knife edges of the drum B, carries it round with it, first deflecting under the resistance until the force with which it tends to recover itself is equal to that resistance. This deflection being measured, measures the resistance to be overcome to drive the machine, and the space travelled by the point where it is applied, measures the space through which that resistance is overcome.

The registration of these measurements, under every change of resistance and motion to which the machine may be subjected, is effected as follows:—

A radial frame, fixed to the axis, carries three rollers, r, q, s, round which passes a long strip of paper, winding (when the rollers are put in motion) off r and on s, passing between them, over q. To put them in motion a bevel wheel, whose axis—at right angles to the axis of the dynamometer—has its bearings fixed to the frame, so as to be carried round with the axis of the dynamometer, engages with another bevel wheel, which runs loose on the axis of the dynamometer, and which is held at rest by a fixed bracket. The bevel wheel carried round by the frame and engaging in this fixed bevel wheel, carries with it the roller r, and obviously communicates to it, and therefore to the strip of paper, a motion proportional to that of the point where the spring presses on the knife edge. The roller s is made to take up the paper thrown off by r, by means of a spiral spring inclosed in it. The strip of paper being thus understood to pass over the roller q with a motion proportional to that of the point of application of the pressure which drives the machine, let it be observed that on an arm of the drum A is fixed a style, carrying at its extremity a pencil, which is pressed by a spring upon the paper passing over the roller q. When the strap which the drum B drives is taken off, that drum

referred to the "Leçons de Mécanique Pratique," of M. Morin.

is carried round by the drum A without resistance; there is, therefore, no deflection of the spring, and no turning of the pulley upon the axis consequent upon that deflection. The trace of the pencil upon the paper will, under these circumstances, be a straight line; and in all experiments the pencil is made first to trace such a line.

When, however, the strap is replaced, and the work is put on the drum B, the latter turns upon its axis, pressing the spring upon the knife edge, and deflecting it until its resistance is equal to that opposed by the machine driven by the strap. By this turning of the drum the pencil is moved at right angles to the line which it before traced on the strip of paper, by a space proportional to the deflection of the spring, and, therefore, to the pressure by which the spring is deflected; and this proportion being maintained, however the pressure may be varied, an irregular curved line is traced upon the paper, whose distance from the straight line before traced upon it, is always proportional to the pressure by which the machine is driven; whilst the corresponding distance along the straight line previously drawn, being measured from the commencement of the motion, is proportional to the space described by the point of application of that pressure. Hence it is apparent that, as in the case of the common steam-indicator, the area of the curvilinear space between the straight line traced by the style before the work was put on, and the curved line traced by it afterwards, is proportional to the work done in driving it. There are two other contrivances worthy of notice.

1st. A contrivance for correcting the want of uniformity in the motion of the paper, produced by the diminution of the diameter of the roller as more of the paper winds off it. This correction is rendered necessary by the great length sometimes given to the strip of paper. This correction is effected by the intervention of a fuse-wheel.

2nd. An admirable method of M. Poncelet for registering in numbers in one part of the dynamometer the work which in another (as described above) is registered, under the form of a curvilinear area. This is effected on a principle, which has also been applied to the mechanical quadrature of areas, in an instrument called the planimeter, of which several are exhibited in the department of Philosophical Instruments. The two registrations serve to verify one another.

#### AWARDS IN SECTION G.

No. 1151, p. 1233 (France). P. CLAIR, 93 Rue de Cherche Midi, Paris. 1. MM. Poncelet and Morin's rotary dynamometer. 2. Lapointe's constant indicator. 3. Clair's indicator. The award is made for good and intelligent workmanship in the construction of these machines, under the direction of MM. Poncelet and Morin. Among the articles exhibited by M. Clair is also an admirably constructed model of a locomotive engine in metal, the working parts of which are opened or shown in section, for explanation and instruction.

No. 761, p. 1216 (France). J. BÉRANGER and Co., Lyons. Scales, weighing-machines, and various other implements for weighing. Guided by an ingenious mathematical theorem, M. Béranger has so combined a system of levers that he can place one of his scale-pans at any distance from the other—according to this form he wishes to give to his weighing-machine—without affecting the equality of weights which balance in the two scale-pans.

This combination of levers is simple, economical, compact, and admits of a ready application to all purposes of commerce. M. Béranger has, in fact, made that application in the collection of convenient and ornamental weighing-machines which he exhibits.

No. 944, p. 1225 (France). PARENT, 33 Rue des Arcs, Paris. Weighing-scales, weights, and measures, which have many of the more important characteristics of in-

struments made for philosophical and chemical purposes, and a degree of precision and accuracy is thus attainable for the purposes of commerce, which is not to be looked for in common balances. The award is made for an attempt to improve commercial balances, and for the admirable workmanship of those exhibited.

No. 105, p. 1013 (Austria). H. D. SCHMIDT, Vienna. Model of a patent weighing table.

The mode of suspending the platform on a quadruple lever, and of connecting this lever with the steelyard, is the same as usual. But a very advantageous arrangement is made for relieving the steel fulcrum of the levers, when the machine is not in use, from the weight of the platform, and of any carriages passing over it. Under the points where the platform rests are the four levers; these levers have stout projections or bosses projecting downwards, and nearly touching the upper surfaces of four short pillars of iron fixed into the masonry at the bottom of the pit. When the machine is not required for weighing, the long end of the lever is lowered, together with the steelyard counterpoise and framework, by means of a winch and screw, until the bosses of the levers rest on the pillars beneath them. The weight of the platform and any carriage upon it is then borne by these pillars, and not by the steel fulcrum of the fourfold levers. These fulcrum are thus saved from much unnecessary deterioration. On raising the frame with the steelyard and the end of the long lever, the weight of the platform is thrown on its fulcrum, and the machine is then ready for use.

No. 774, p. 252. JONATHAN DAVIDSON and Co., Baron's Street, Edinburgh, Inventors and Manufacturers. The steelyards and weighing-machines of these exhibitors are manufactured in a very creditable manner. The parts appear well proportioned; and care has been taken to prevent deterioration, as far as possible, by applying steel at all the points peculiarly exposed to wear. The arm of the steelyard is truly balanced on the fulcrum, and is marked off in equal divisions. Hence the scale is available for any counterpoise, as the several weights read off merely show multiples or sub-multiples of the counterpoise. The arrangements and proportions of the several parts are judiciously determined, and the whole is well finished.

No. 784, p. 253. H. POOLEY and Son, Liverpool, Inventor and Manufacturer. Patent weighing-machines. These are remarkable for simplicity, neat and effective construction, and good workmanship. The principle is alike in all. The weighing platform rests on four points, very near the fulcrum of a quadruple lever, as in the common street weighing-machine. One of these fourfold levers is prolonged, and at its extremity is connected with the short end of the lever, to which the scale-pan with its weights, or the sliding counterpoise, is attached.

The locomotive weighing-machine appears very deserving of notice. This consists of a system of three such tables, placed so that a locomotive running over them may have each pair of its wheels on a separate table. Then the three counterpoises may be adjusted until each one correctly balances the proportion of the weight bearing on its table. A bar with a light lever, and a handle projecting from it over each steelyard, enables the attendant, standing opposite the centre one, to check the vibrations of all three, and inspect with accuracy the state of adjustment. By the use of this multiplied weighing-machine the proportion of weight borne by each pair of wheels may be tested, and the inquirer is thus enabled to alter the adjustment of the springs until he has secured such a distribution of the load as may be most likely to lead to good working.

No. 772, p. 252. DAY and MILLWARD, 118 Suffolk Street, Birmingham. Patent weighing-machines. The award is made for simplicity of construction and cheapness.

## CLASS VA.

REPORT ON CARRIAGES GENERALLY, NOT INCLUDING THOSE  
CONNECTED WITH RAIL OR TRAM ROADS.

[The figures after the Names (between parentheses), refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

## Sub-Jury for Carriages.

The Earl of JERSEY, *Chairman*, 38 Berkeley Square.  
J. HOLLAND, *Deputy Chairman and Reporter*, 258 Oxford Street; Coach-builder.  
M. ARNOUX, France; Engineer.  
T. HUTTON, Summer Hill, Dublin; Coach-builder.  
● McDANIEL, United States.  
ANTOINE PONCELET, Belgium; Engineer-in-Chief.

By the "Instructions from the Council of Chairmen to the Juries," we are directed to consider the articles coming within our province for examination, under two divisions, and to regard as qualifications of merit in the first class, or, "carriages of luxury" especially, a "successful application of any new material, with elegance of design, and excellence of workmanship, strength and lightness, and reasonable cheapness;" and in the second class, or "carriages for the public service," lightness, sufficient solidity for safety, durability, and cheapness.

Our examinations and awards have been made in strict conformity with these Instructions.

We find that the contributions in our department are apportioned among various countries as follows, viz. :—

|                | Contributors. | Carriages. | Bath Chaises. | Hewess. | Omnibuses. | Velocipedes. | Sleighs. | Drolschaks. |
|----------------|---------------|------------|---------------|---------|------------|--------------|----------|-------------|
| Great Britain  | 69            | 79         | 11            | 2       | 2          | 3            | —        | —           |
| France         | 5             | 5          | —             | —       | —          | —            | —        | —           |
| Belgium        | 4             | 7          | —             | —       | —          | —            | —        | —           |
| Hamburgh       | 1             | 1          | —             | —       | —          | —            | —        | —           |
| Prussia        | 2             | 2          | —             | —       | —          | —            | —        | —           |
| Grand Duchy of | 1             | 1          | —             | —       | —          | —            | —        | —           |

| Turkey         | 1             | —          | —             | —       | —          | —            | 1        | —           |
| Canada         | 5             | 1          | —             | —       | —          | —            | 5        | —           |
| United States  | 8             | 8          | —             | —       | —          | —            | 1        | —           |
| Total          | 100           | 107        | 11            | 2       | 2          | 3            | 9        | 3           |

(Messrs. J. HUTTON and SONS, of Dublin (884, p. 257), exhibit four carriages, which are excluded from competition as Mr. Hutton is a Juror in this class.)

Besides the articles in the foregoing table, we have had under examination a number of *models* of minor importance, patent axles, wheels, and other parts of carriages, coach-lace, &c., the peculiar merits of which are not sufficiently evident to entitle them to special notice or commendation.

The fact most obvious in the display of carriages is the want of variety in the kind, and the absence particularly of the higher class of equipages, of travelling carriages, properly so called, and of vehicles intended "for the public service." The dress or plain: *vis-a-vis*, the dress or plain coach, the landau, the mail-coach, &c., have no representatives in the Exhibition.

We confess we are somewhat surprised at the deficiency in this respect; but regard it as accounted for in a great measure by the demand for carriages of these descriptions having been so materially diminished by the general introduction, within a recent period, of railways.

We are also of opinion that the trade is not fairly any

more than fully represented, and that the art of carriage-making has attained a point of excellence which would warrant the expectation of a higher standard of merit than is shown in the Exhibition. While we recognize very generally the use of superior woods, leather, and other materials, in the construction of carriages, the most admirable workmanship, and a nice attention to details, we perceive many defects in style, and the display frequently of bad taste. There is often an injudicious expenditure on costly ornament and elaborate finish, which are incompatible with the serviceable class of carriages to which they are applied. In many instances this is carried to an extent that mars instead of enhancing the beauty of the vehicle, and besides increasing the cost, is a positive detriment.

Comparing the state of the art of carriage-building of former and not very distant times with that of the present, we consider the principles of building in many respects greatly improved, and, particularly with reference to "lightness" and a due regard to "strength," which is evident in carriages of British make, and especially displayed in those contributed by the United States, where there is commonly employed in the construction of wheels and other parts requiring "strength and lightness" combined, a native wood (upland hickory) which is admirably adapted to the purpose. The carriages from the continental States do not exhibit this useful feature in an equal degree.

We observe many innovations and contrivances in springs, steps, fore-carriage locking movements, &c., which are not always improvements, and yet convenience and nice adaptation have been much advanced in these respects also within a few years. We notice a justly meritorious and very nice automatic step on the carriage of Mr. David Davies of London (824, p. 256), and an ingenious spring door-lock on a carriage of M. Moussard of Paris (657, p. 4209).

In our judgment the appearance of the carriage has not been improved by a deviation quite common from the lines hitherto adopted and approved, and we regret to remark, under the head of "elegance of design," that we find in the exhibition of carriages a great deficiency. While we admit, therefore, that there has been considerable progress in the principles of carriage-building, we are of opinion that the style has been injured by injudicious innovation.

We are aware that the coach-builders of the present day have had no easy task to perform, in meeting the new demands of the age, which require them to construct vehicles to convey the greatest number of persons. It can hardly be expected that in carriages of such a description they can preserve those outlines which have been esteemed elegant and graceful. It is to be deprecated, however, that this necessity in some cases, of departure from the rules approved by good taste, should be displayed in the higher class of carriages of pleasure and luxury, since these must be exempt from the difficulty referred to; and it is to be hoped that future innovations in that direction will be governed by a nice discrimination, pure taste, and sound judgment.

We do not observe that there has been, what may be properly considered, a "successful application of any new material," although we may mention the application recently of a band of caoutchouc around the rim of carriage wheels, in order to render them "noiseless." This application may be useful to a limited extent on light carriages, but it is of very doubtful general utility, and does not appear to be adapted to long or hard street service. We are pleased to see the general use of very superior patent and enamelled leathers, combining in a remarkable degree, pliancy and water-proof qualities. This is conspicuous in the contributions of Great Britain, France, Belgium, and the United States. The iron-work is also generally of the best description, in point of quality of the metal and the execution, but in many cases it lacks due simplicity in form and arrangement of some of the parts. The perfection which textile manufacture has attained of late years, has had a corresponding effect on the interior fittings of carriages, which in linings, &c., are now beautifully appointed at a comparatively moderate cost.

The consideration of "reasonable cheapness" has been duly observed; but it is obviously very difficult to determine the exact intrinsic value of an article like a carriage, and to judge positively whether the affixed price is excessive or not. The cost is often much increased by ornament, finish, or contrivance, that might be advantageously dis-

pensed with, and thus a carriage, otherwise extravagant in price, be reduced to a standard of "reasonable cheapness." And this useless addition of expense is a fault of common occurrence to which we have previously alluded. Extravagant prices may fairly diminish the claim for approval; but at the same time we are convinced that what may be deemed high prices are not always exorbitant prices, but that with carriages as with articles of household furniture, the most similar perhaps to those under our notice where the quality of the article is more or less concealed, the lowest priced may often prove to be the dearest purchase.

After a patient, and we believe thorough examination, we are unanimously of opinion that there is no contribution among the articles in our department which possesses such "pre-eminence and indisputable merit" (Sec. 20, Instructions) as to be entitled to the "Council Medal," and therefore we do not recommend that this distinguished award be bestowed on any. But while we withhold the highest mark of merit, from a sense of duty, we do not deny the prominent claims of many contributors to distinction; and we have endeavoured to select those upon which we think we can confer with the greatest justice the only mark of merit at our disposal. A list of contributors, to whom we award the "Prize Medal," is subjoined.

## CLASS VI.

### REPORT ON MANUFACTURING MACHINES AND TOOLS.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

#### Jury.

General J. V. PONSSELET, *Chairman*, France; Member of Institute, late Director of Polytechnic School, &c.  
 Rev. H. WILLIS, M.A., F.R.S., &c., *Deputy Chairman and Reporter*, Jacksonian Professor of Natural and Experimental Philosophy, Cambridge.  
 Professor FILIPPO CORRIADI, Tuscany; Director of the Technological Institute, Florence.  
 LUIGI DE CRISTOFORIS, Austria; Vice-President of Chamber of Commerce, Milan; Member of the Scientific Institute of Bologna.  
 BENJAMIN FOTHERGILL, Manchester; Mechanical Engineer.  
 CHARLES GACQUIGNY MACLEA, Leeds; Mechanical Engineer.  
 GUILHERME KOPKE, Portugal; Mechanical Engineer.  
 JOHN PENN, Greenwich; Mechanical Engineer.  
 GEORGE RENNIE, F.R.S., Whitehall Place; Mechanical Engineer.  
 T. R. SEWELL, Carrington, near Nottingham; Lace Manufacturer.  
 SAMUEL WEBBER, United States; Civil Engineer.  
 Professor W. WEDDING, Zollverein; Member of the Board of Trade and Commerce at Berlin.

#### Associates.

A. BANCLAY, Brewery, Park Street, Southwark; Brewer.  
 ROBERT DAVISON, 33 Mark Lane; Civil Engineer.  
 — DOLFOUSER, France.  
 J. MERCER, F.C.S., Oakenshaw, near Accrington, Lancashire; Calico Printer.  
 A. PAYEN, France; Member of the Institute.  
 Dr. VALENTHAFF, Zollverein; Professor of Chemistry.

THE Jury for "Manufacturing Machines" have inspected the articles contained in that Class of the Exhibition, and have to Report thereon as follows. —

They find it to contain a collection unparalleled for number, importance, ingenuity, beauty of execution, and every quality by which the machines of the present day are distinguished; but they desire carefully to guard against the supposition that every branch of manufacturing mechanism is represented. On the contrary, great inequality prevails in this respect; some manufacturing processes being abundantly and almost superfluously illustrated, others wholly omitted, and the remainder represented by very few specimens.

The textile processes in general, the preparation and spinning of cotton, flax, wool, and silk, weaving in all its branches, are, for the most part, well illustrated by the public spirit of various exhibitors, who have not only sent complete series of the respective machines, but also maintain them in motion, doing work, so that these materials are actually shown to the visitors in their gradual progress from the raw state to the saleable product. But even in this division many machines are necessarily omitted, especially if the nature of their work unfits it to be carried on in the presence of a crowd of spectators.

Such are the preparatory washings and cleansings of raw material; all kinds of fulling, calendering, dyeing, and the like, which either derive their sole interest from processes that are accompanied by excessive noise, dust, disagreeable smells, splashing and spilling of water and other liquids, or similar annoying phenomena; or are of such a nature as to occupy time, or demand more care than can be bestowed in the presence of an assembly of spectators; or which require peculiar conditions of temperature or other arrangements incompatible with public exhibition. Paper-making may be placed under this head, and consequently only a few of its models and machines are exhibited; and these at rest.

For completeness and value, the collection of machine-tools for working metal and wood may take its place next to the textile mechanism; and here may be seen specimens of nearly every class of the engines that have been introduced in the present century by our machine-makers, and by means of which the construction of the vast and

complicated machinery that now pervades all classes of industrial occupations has been rendered possible. But the magnitude of the work usually executed by such engines—the steadiness of foundation which they require, and which is unattainable in this building—and other considerations appear to have prevented the exhibition of their action; for although they are placed in the department of machines in motion, and some of them are actually kept in motion in part, no work is placed upon them. For obvious reasons, all processes of working metal which require heat are impracticable, and very few of the machines which belong to such are here to be found. Thus the reduction of metals from the ores to bars and sheets, and all founding or casting processes, are wholly unrepresented, as well as the curious and interesting operations belonging to the glass and pottery manufactures. To these may be added machines which are so bulky or so easily deranged as not to justify, in the opinions of their owners, the risk and expense of removing them to the Exhibition, or the sacrifice of the work which they are producing in their own manufactories.

A great variety of printing processes will be found in the collection, many of them maintained in constant action; also many mills for grinding and crushing vegetable products, with the cleansing and sifting apparatus connected with them; but of course not exhibited in action. Besides these, there are various miscellaneous machines which will be indicated as we proceed. Enough, however, has been said to show that the present collection does not represent the real extent to which machinery is employed in the manufactures of this country, seeing that, at all events, those machines are omitted which derive their sole interest from the processes with which they are connected, and when these are of such a nature as to forbid their being carried on in the presence of an assemblage of spectators or in an ornamental building. It will be remarked that the greater part of the machines which are exhibited are sent by their makers and not by manufacturers.

The above remarks are more especially directed to the British part of the Exhibition; but they apply with still greater force to the foreign, in which the expense of the respective countries and the risk of damage to the

which have been sent to the Exhibition, are of the most valuable and delicate objects of this kind. Notwithstanding the considerable number of valuable and ingenious machines that are placed in the eastern division of the building, any attempt to estimate from this collection the relative employment of machinery in any branch of manufactures by their respective countries, or the relative standard of excellence which each has attained in the construction and contrivance of machinery, would lead to the most fallacious and unjust conclusions.

The machinery of the Exhibition, and the foreign machines especially, must therefore be looked upon as a collection of miscellaneous articles, sent by individuals without any principle of concurrence or any attempt to secure the fair and equitable representation of every class of manufacturing machinery, or of the styles and mode of workmanship which prevail in different countries or districts.

It will of course be understood that the above remarks are strictly confined to the articles which belong to the class of manufacturing machines; for the portions of the building wherein they are placed also contain many of those that are included in Class V., especially in the foreign departments, in which the machines of the two Classes V. and VI. are also mixed up with agricultural and other mechanism of all kinds, and with hand-tools and manufactured articles that properly fall under the denomination of "cutlery" or "general hardware." Many machines which are inserted in the Catalogue have not been sent by their respective exhibitors, or they prove upon inspection to be either models of small importance, or to have been so deranged by the transit as to make it impossible to set them in motion, or form any just opinion of their merits, especially in cases where the exhibitor is neither to be found, nor has left any representative capable of explaining them.

In round numbers it appears that the English exhibitors amount to about two hundred and twenty. France has contributed between fifty and sixty; the United States, fifteen; Belgium and the Zollverein, ten or twelve each; Russia and the Netherlands two or three; while Sardinia and Switzerland have merely sent some machine-tools used in the manufacture of watches. Since it thus appears that the machines sent by each country, whether British or foreign, bear no proportion to the relative employment of machinery, considered either with respect to geographical distribution or to the different departments of manufacture, it will be useless to examine each country by itself. In the following more detailed survey of the collection, the machines will be classed according to their functions, including under each head all those that have been contributed by the different nations.

(A.) CONVERSION OF RAW MATERIAL INTO A CONTINUOUS THREAD, AND SUBSEQUENT PROCESSES.—(1.) Cotton.

(2.) Wool. (3.) Flax and Hemp. (4.) Silk.

(B.) WEAVING OF ALL KINDS.—(5.) Looms. (6.) Lace-frames. (7.) Knitting or hosiery frames. (8.) Head machines, sewing machines, &c.

(C.) PAPER AND PRINTING.—(9.) Making, cutting, and folding paper. (10.) Type printing. (11.) Numbering, paging, and ruling machines. (12.) Lithographic and copper-plate presses.

(D.) WORKING PARTS OF THE ABOVE MACHINES.

(E.) MACHINES FOR WORKING IN METAL, WOOD, SPONGE, CLAY, LEATHER, &c. &c.—(13.) Lathes for metal (including also those for wood, &c.). (14.) Machines for planing. (15.) Shaping. (16.) Shaping. (17.) Drilling and boring. (18.) Other machines and tools for working metal. (19.) Machines for sawing, planing, mortising, &c. wood. (20.) Working in stone materials, as stone, coal, clay, leather, glass, &c.

(F.) MILLING AND GRINDING AND SPLICING FIBRE, AND OTHER VALUABLE PROCESSES.—(21.) Grinding. (22.) Slicing.

(G.) MACHINES FOR THE MANUFACTURE OF SOAP.

(H.) APPARATUS FOR DISTILLING, CONDENSING, AND MANUFACTURING CHEMICALS.

We cannot describe the numerous machines with-  
out expressing our warm thanks to the exhibitors.

whose zeal, ability, and diligence, we have been so greatly indebted throughout the whole period of our labours.

#### (A.) CONVERSION OF RAW MATERIAL INTO A CONTINUOUS THREAD, AND SUBSEQUENT PROCESSES.

##### (1.) Cotton.

In the exhibition of machinery for spinning, and its preparatory processes, Messrs. HIGGINS, FARR, and SONS (1, pp. 263-268) have taken the lead, by establishing and maintaining in operation a complete series, beginning with the opening machine and slubber, and including the various carding engines, the drawing, slubbing, and roving machines, two self-acting mules (the one adapted to the left, the other to the warp), and also a throstle, a winding-machine, and a doubling machine. This splendid series of nineteen machines is of their own manufacture, and contains many improvements on the ordinary constructions, besides affording a complete picture of the progress of the raw material from the state in which it is imported, to that in which it is delivered to the weaver. Attention must also be directed to the beauty and excellence of the mill gearing and its framings, by means of which these various machines receive their motion from the steam-engine. This part of the work is exhibited by Messrs. HIGGINS and SONS, of Bolton (1, p. 268). The cotton cleaning and opening machine of the above series is on Mr. F. A. CALVERT's construction, who also exhibits (27, p. 271) other specimens of his new and effective method of making wool-burring, cotton cleaning, and carding cylinders.

Other makers have sent admirable specimens of some of these machines, each distinguished by peculiarity of construction, important improvements, or beauty of workmanship. Amongst these the new throstle of Messrs. SHARP, BROTHERS, and CO. (15, p. 270), is remarkable. The principle of this machine, which is derived from America, is—that a small loop running on a ring is substituted for the usual flyer, whence it is termed "the ring and traveller throstle." The framing and disposition of its parts are greatly improved by the present makers.

Messrs. HIGGINS and SONS (14, p. 270) exhibit their roving-frame, and Mr. J. MASON (10, pp. 268, 269) a drawing-frame, a roving-frame, and a slubbing-frame, furnished with their patent collars, by which the spindles revolve with greater steadiness, and an increased velocity can be attained. Also separating plates for the slubbings, and a brake motion for more effectually stopping the machine. Messrs. FARR, CURTIS, and MADELEY (6, p. 268) exhibit an extensive contribution of machines, including a carding-engine, drawing, slubbing, and roving-frames, and three patent self-acting mules, each of a different construction. A new self-acting mule is also shown in operation by Mr. G. P. MACINTOSH (24, pp. 270, 271), in which a radial arm is employed to produce the return motion, or putting-up of the carriage. Mr. R. SCHILLER (42, p. 273) exhibits a doubling-frame of an improved construction, in which the flyer is drawn by the bobbin, and other arrangements are carried out for the purpose of obtaining a high velocity. Messrs. GARNER and HANLEY (37, p. 272) contribute a small doubling-frame for lace thread, in which the spindles are driven by contact wheels in lieu of hands, an arrangement that has also been used in the throstle of Messrs. SHARP already described. Mr. PATTERSON (23, p. 271) exhibits a machine for whirling cops: M. DE FONTAINE MOREAU (p. 278) a mode of driving spindles with tooth gear, and Messrs. LEWIS and M'LANDY (209, p. 292) a spindle for roving, slubbing, or doubling, which combines the advantage of top bearings with facility of doffing.

The Foreign Department contains very few machines for the manufacture of cotton.

Mr. ROULEX (France, 1438) exhibits a machine, which he terms "L'Épandeur," for opening and cleaning cotton upon a new system, that promises great advantages, and Messrs. SHARP and CO. (France, 1031, p. 1337) contribute a large roving frame, of excellent workmanship, in which the spindles are whirled round by spur-

wheels. From Belgium, the PHOENIX COMPANY (134, p. 1155) have sent a well-made "off-bobbin" frame, in which the cone and pulley, usually employed to produce the variable motion required by the bobbins, are replaced by a group of four-wheels. Mr. W. HAYDEN, of the United States (386, pp. 1461, 1462), exhibits a drawing-frame for cotton, with an ingenious self-acting mechanism for regulating the weight of the slubbing, and Messrs. BATES, HYDE, and Co. (440, p. 1463), send a saw-gin for cotton. Messrs. W. and C. MATHER (46, p. 270) exhibit a calico-printing machine, for printing eight colours at one operation.

### (2).—Wool.

The machinery for the woollen manufacture, notwithstanding its extent and importance, is very slenderly represented. Mr. G. E. DONISTHORPE (40, p. 273) contributes a machine for long-wool combing, recently patented, on a new principle, of great ingenuity and admirable promise; and Messrs. BERRY and SONS (48, p. 274) have furnished a series of the six machines employed in the manufacture of worsted yarns, of the best workmanship and of improved construction. By these the complete progress of the material, from the state of a sliver to the spinning, inclusive, is shown in daily operation. Mr. MASON (46, pp. 268, 269) exhibits, in the short-wool department (or clothing branch), two carding-machines and a mule. These deserve especial notice, as being on the plan now adopted very generally on the Continent, and universally in the United States, by which endless slubbings are formed directly from the card. The old billy-machine, and the operations connected with it, are thus dispensed with, and the yarn produced is more level. Mr. MASON'S machines contain several important improvements, of his own invention; especially an apparatus for condensing the slubbing from the first card. In the French Department, a set of woollen machinery, on the same system, is exhibited by Messrs. MECIER and Co., of Louviers (332, p. 1208); namely, two carding-machines and one semi-self-acting mule. These machines are of highly-finished workmanship, and in the best style of modern French machine building. In this department (283, p. 1190), Messrs. LACROIX and SONS contribute a fulling-machine, of admirable construction upon a system which has entirely superseded, on the Continent, the old method of fulling-stocks. In the English part, Mr. E. HUNT (49, p. 274) exhibits a gig-mill, of a new and simplified construction, which, by working on both sides, and thus finishing the process of dressing with teasels, without removing the cloth from the machine, is rendered capable of turning out considerably more work than on the usual system.

The English mechanists have not contributed a single shearing-machine, but in the Foreign Department there are exhibited several of very creditable workmanship; namely, by Messrs. THOMAS (Prussia 57, p. 1060), H. THOUFIN BROTHERS (Belgium, 128, p. 1155), and SCHNEIDER and LEGRAND (France, 1001, p. 1227).

### (3).—Flax and Hemp.

The Flax manufacture is represented, in the present collection, with the same spirit and completeness as the cotton.

Mr. R. PLUMMER exhibits his patent rotatory disc machine (74, pp. 275–277), with other machines for breaking, cutting, and dressing flax; also his application of gutta percha to the holders. Messrs. LAWSON and SONS contribute a set of sixteen machines (75, pp. 277, 278), which, for beauty of execution, value and completeness of illustration, are fully equal to those which Messrs. HUBERT have furnished in the department of cotton. These machines are divided into three series, that include the three departments of flax manufacture; namely, the tow, the long flax, and the cut flax; and they contain all the machines used in each respectively, by which the raw material is converted from the form in which it is imported, to the thread, as delivered to the weavers, or others, by whom it is employed. Among them are the machines by which the spinning of flax has been so greatly facilitated by substituting cold water for warm,

which was formerly employed to the great detriment of the health of the workpeople. Messrs. HIGGINS (14, p. 270) have also exhibited excellent specimens of the four machines employed in the long flax spinning, and the preparatory steps which belong to it.

In the article of Hemp we find only the large machine of Mr. J. CRAWHALL (78, p. 279), by which yarns, spun by processes not exhibited, are converted into a rope. This machine, compared with the previous ones, from which it is derived, is remarkable for simplicity of arrangement.

The Foreign Department does not contain a single machine relating to the flax manufacture.

### (4).—Silk.

The simpler machinery of the silk manufacture is completely exemplified by the beautifully-finished machines of Mr. J. L. DAVENPORT (80, p. 279), which include the complete series employed in that branch, for throwing, winding, cleaning, spinning, doubling, and reeling; the whole of which are exhibited in operation. Mr. J. FROST (84, p. 279) also contributes models (or rather, short portions) of his improved machines for winding, cleaning, throwing, &c., and of his spinning and doubling machine, in which the two operations are performed by one process.

In the Zollverein Department is a machine for silk-winding, by Mr. T. H. DREPPERS (472, p. 1078); and in the Russian (150, p. 1371), a machine, by Mr. H. GRAFF, for spinning silk directly from the cocoon.

Attention must also be directed to the ingenious machines for manufacturing the cards with which the carding-machines for cotton-wool, &c., are clothed. Two specimens of this machine are exhibited, the one in the English Department, by Mr. T. CRABTREE (3, p. 268); the other in the French, by Messrs. PAPAYOINE and CHATEL (339, p. 1193), both of excellent workmanship, although differing very little from the well-known machine of Mr. DIER.

From this rapid survey of the machinery in the Exhibition, for converting the raw materials of cotton-wool, flax, and silk, into a continuous thread, it appears that nearly all the processes are represented, and some of them in the most satisfactory and complete manner. It is to be regretted that no specimens have been sent of the curious machines, by which caoutchouc is manufactured into a continuous line.

### (1).—WEAVING OF ALL KINDS.

#### (5).—Looms.

We may now proceed to the various classes of looms, of which a great variety are placed in the Exhibition, and most of them maintained in operation, either by power or hand; many of them also are remarkable for novelty of construction and for important improvements, which can only be alluded to, here, as it would be impossible to render them intelligible without the aid of drawings or very long descriptions. Those, however, which appear of the greatest importance may be mentioned.

Messrs. C. E. and C. PARKEN'S power-loom for sail cloth (77, p. 278) is distinguished by peculiar and effective arrangements for maintaining the uniform and regular delivery of the warp, and a constant but adjustable tension in the taking-up motion, by which the firmness of this important article of manufacture is insured.

Mr. BROWN (56, p. 275) also exhibits a sail-cloth power-loom with peculiar arrangements, adapted to the same objects.

In Mr. BARLOW'S double jacquard loom (82, p. 279) two cylinders are employed, and the cards are disposed upon these in alternate order, so that, while one cylinder with its cards is brought into action upon the horizontal wires, the other is withdrawn for the purpose of rotating it, and shifting the card, and *vice versa*. By this arrangement the loom can be worked with a velocity 40 per cent. greater than that of the ordinary construction; the steadiness of its motion is greatly increased, and the strain upon the warp diminished, by another improvement, which consists in lowering the warp threads as well as

raising them; whereas in the ordinary jacquard loom those threads which are not carried up by the lifting bars are allowed to remain in the horizontal position.

The power-loom of Messrs. KENWORTHY and BULLOUGH (21, p. 270) is characterized by two self-acting methods of stopping the loom by throwing off the belt; the one when the web breaks, the other when the shuttle *traps*—that is, sticks in its course through the shed.

Mr. MASON's large loom for wool (16, pp. 268, 269), has a motion which releases the swell of the shuttle-box at the instant of *picking* or driving the shuttle, whereby the force required for the latter operation is greatly diminished.

Mr. M. SMITH (22, p. 270) exhibits several power-loom with a peculiar mode of delivering the warp; one of them has a self-action for changing the shuttles, and thereby working in three colours in any desired order, the changes being governed by a kind of jacquard apparatus.

Mr. FROMAGE (France, 219, p. 1184) contributes a power-loom in which two shuttles are employed, and shifted by an endless chain, provided with tappets fixed in the order required by the pattern.

Messrs. TAYLOR and SON's power-loom (23, p. 270) is provided with four jacquard cylinders working simultaneously, and Mr. CHALMERS (32, p. 273) exhibits a large power-loom for damask-weaving, provided with a jacquard and some new arrangements.

Mr. CRITCHON's model (35, p. 273) shows a taking-up motion that adjusts itself to the increasing diameter of the cloth beam with more precision than any previous contrivance.

Other looms are exhibited by Messrs. HARRISON (18, p. 270), HENNING (43, p. 275), ELLIOTT and HEYS (50, p. 274), MILLIGAN (38, p. 273), CROSS (64, p. 275), and J. SMITH (59, p. 275).

A jacquard loom of the most beautiful workmanship and mechanism, for weaving silk-flowered damask of the richest quality, is maintained in constant action by Messrs. ATKINSON and CO., of Dublin (12 and 15; and the LOWELL MACHINE SHOP have sent from America (447, p. 1464) a power-loom of highly-finished workmanship. The power-loom for weaving fringe by Messrs. REED and CO. (85, p. 279), is a remarkable piece of mechanical contrivance, weaving without shuttles thirty-four pieces of fringe simultaneously.

Mr. HARRISON (18, p. 270), exhibits a power-loom made fifty or sixty years ago, which will be looked upon with great interest as a specimen of the mode in which machinery was constructed at that period.

Notwithstanding the great employment of the jacquard loom in France (the country to which the world is indebted for this admirable piece of mechanism), the only specimens that have been sent from thence on the present occasion are two jacquard cylinders by Messrs. MARTIN (123, p. 1192), and ACKLIN (399, p. 1197), which exhibit two different ways of employing a continuous sheet of paper in lieu of the chain of pasteboards usually applied.

Well-made jacquards of the ordinary construction are exhibited in the Zollverein Department by Messrs. WINTER (56, p. 1050), and BONARDEL BROTHERS (53, p. 1050); in the Austrian, by the Heirs of P. GAMBA (109, p. 1013), and in the Russian by the IMPERIAL ALEXANDROVSK MANUFACTORY (149, p. 1371); from Belgium, M. VAN DEVELIN (126, p. 1155) sends a singular loom in which a pattern, painted on soft cloth, is employed in a kind of jacquard-frame to act instead of the chain of cards; this simple device appears to succeed well enough for coarse damask, linen, and other common goods.

Various applications are shown of small jacquard machines which act on the heddles of power-loom in lieu of tappets, or in other ways, so as to produce diapers or other figured patterns of limited range; as, for example, by Messrs. GOUDEAU (Belg. 135, p. 1155), M. SMITH (32, p. 270), J. SMITH (59, p. 275), MASON (10, pp. 268, 269).

A simple machine for reading the jacquard patterns and punching the cards, well adapted for small weavers, is shown by Messrs. BONARDEL (Prussia, 53, p. 1050), and a reader with keys similar to those of an organ, by Mr. MACKENZIE, (39, p. 273).

Mr. DE FONTAINE MOREAU (30, p. 273) exhibits a jacquard loom, in which a cylinder like that of a barrel organ, and provided with pegs that can be shifted to suit any required pattern, is substituted for the usual chain of cards.

#### (6.) Lace Frames.

Mr. BIRKIN (94, p. 280) exhibits, in operation, a single tier jacquard bobbin-net machine, making figured laces. This machine is of excellent workmanship, and most judiciously arranged, combining all the recent and important improvements in this branch of manufacture.

Mr. SEWELL (92, p. 279), one of the jurors of this class, contributes a double-tier bobbin-net machine, making Brussels net, combining great simplicity of arrangement and symmetry of proportion with efficient operation.

Messrs. BALL, DUNNICLIFF, and Co. (90, p. 279) maintain, in operation, a warp-lace machine, making silk blond, of excellent workmanship and design, and remarkable for the noiselessness of its complex movements.

A frame for "gassing lace"—that is, for burning the minute fibres from it by passing it rapidly over gas flames, is exhibited by Messrs. HUDSON (96, p. 280); but they are unfortunately prevented from showing this most interesting process by the necessary restrictions against the introduction of gas into the building.

Messrs. HUDSON and BOTTOM (88, p. 279) show a lace-dressing machine of superior construction, but are also prevented from exhibiting its operation by the unsuitableness of the process.

#### (7.) Stocking or Hosiery Manufacture.

In this Department are several machines, both English and foreign, well worthy of remark. Messrs. T. and T. G. CARVER (89, p. 279) exhibit a well-made and beautifully-finished stocking-frame of the ordinary form.

Messrs. WHITWORTH and Co. (201, p. 287-290) show their machine for knitting, in which the stitches are taken up singly, as in hand-knitting. This machine (the principle only of which is American) is remarkable as a specimen of English constructive propriety and skill. Somewhat similar in principle is a small machine for knitting seamless purses in the French Department, by M. LANEVILLE (287, p. 1190).

Of circular hosiery frames Mr. CLAUSSEN (86, p. 279) in the English Department exhibits two, and Mr. JACQUIN, of Troyes (546, p. 1204), in the French Department, three. These machines, which are nearly identical, are remarkable for excellence of workmanship and beauty of arrangement. They have vertical sinkers, eccentric depressers, and tucking pattern wheels, and are calculated to produce fabrics of great variety and beauty, and to effect important and beneficial results in this branch of manufacture.

The circular frames of M. BENTHELOT (France, 422, pp. 1198, 1199) are more complex than the above; the sinkers are arranged in a horizontal position, and revolve with the frame; but these machines will produce fabrics of a finer description, and of flax and silk, materials which are intractable in the frames above mentioned.

In the Belgian Department (123, p. 1155) will be found a small circular hosiery frame, by M. JOUVNE.

#### (8.) Hedd Machines, Sewing Machines, &c.

Two machines for weaving heddles for looms are exhibited in this collection.

That of Mr. JUDKINS, in the English Department (52, p. 1274), is an ingenious application of the principle of the common plaiting-machine to the production of a hedd, combined on a new system, completely free from knots or other obstructions to its action, and to the passage of the warp.

The machine of M. DOREY (France, 823, p. 1290) is a beautiful piece of mechanical combination, and the hedd, although different from the above, is also without knots.

Plaiting machines of the usual construction are shown by Mr. VAN MIERLE (Belgium, 133, p. 1155), and M. DORFELL (Prussia, 54, p. 1081).

Under this head we may also notice three ingenious

and useful contrivances in the French Department, namely, a small frame by M. FOUCHER (847, p. 1230) to enable poor workmen or cottagers to weave slippers with ease and rapidity; a frame for weaving wigs by M. CHAISEAT (1874, p. 1252); and a large machine for sewing sacks by M. SENECHAL (373, p. 1194).

An effective and ingenious machine for sewing with two threads is exhibited in action in the American Department by Mr. BLODGET (551, p. 1468). A somewhat similar one is shown by Mr. JUDKIN in the English Department (52, p. 274).

#### (C.) PAPER AND PRINTING.

##### (9.) Paper-making, Cutting, and Folding.

We now come to the curious and useful process by which worn-out and dirty rags, old ropes, and such-like apparently worthless matter, are wrought into paper. But unfortunately, as in many other cases already alluded to, the noise, drump, and heat with which the operations of paper machinery are inseparably connected, have prevented them from being shown, and indeed for the most part the machines are only represented by Models.

Messrs. COWAN and SON (166, p. 286) exhibit a model of a pulp-meter for regulating the supply of pulp to the paper machine so as to insure equality in the thickness of the sheets; Mr. FOURDRAINER (100, p. 280) a model of his original patent paper machine; and Messrs. DONKIN and CO. (130, p. 282) an elaborate and beautiful model of a complete series of machines, with their appurtenances, for making paper, containing all the latest improvements which he has introduced into this important and valuable branch of manufacturing mechanism; Mr. MARSHALL (137) also contributes a model of a paper-making machine.

Portions of the process are illustrated by other exhibitors, as in Mr. WATSON's improved pulp-strainer (165, pp. 285, 286); and in the wove wire-cloth and dandy rollers of Messrs. BREWER (132, p. 282; and 144, p. 283); Mr. SULLIVAN (156, p. 284); and Mr. MARSHALL (137).

A machine for cutting the endless paper into sheets is shown in Mr. DONKIN's model in connexion with the paper-making machine; and one of the full size is exhibited by Mr. TIDCOMBE (108, p. 280).

In the French Department (717) there is a complete suite of paper machinery of the full size and of excellent workmanship, containing all the appurtenances for moulding, drying, laying, and cutting the paper, by Messrs. VARNALL, MIDDLETON, and ELWELL (p. 1213).

Mr. WILSON (112, p. 280) exhibits his admirably constructed and useful machines for cutting paper, card-boards, books, &c. In one of these the knife descends vertically, and in the other, which is more especially intended for mill-boards, it descends diagonally. In the French Department, M. ROTTERIE (1101, p. 1230) has a small cutting-press for bookbinding, in which a knife moves diagonally in a horizontal plane.

Two machines for gumming and folding envelopes are exhibited in operation in the English Department. One, beautifully finished by the original inventor of such machines, Mr. DE LA RUE (Class XVII., No. 76, pp. 541-543), is distinguished by great ingenuity and perfect operation; the other, by Mr. REMONDE, contains a novel application of currents of air and exhaustion to produce the motions of the paper in folding, and the transference of the envelopes.

Mr. BLACK (138, p. 283) has an effective machine for folding printed sheets, whether 8vo., 2mo., or 24mo., newspapers, &c. with precision and rapidity; and Mr. TAYLOR (136, p. 283) a machine by which flat circular discs of paper are neatly moulded into hemispherical lamp shades.

Messrs. CHURCH and GODDARD (135, p. 283) exhibit a machine which cuts sheets of card-board into packs of cards.

The machine of Mr. ANONNO for making cigarettes (448, p. 303) is principally employed in cutting, wrapping, and adding the ends of the paper envelopes in which the tobacco is enclosed, and may therefore be included under the present head. In this beautifully contrived mechanism an endless sheet of paper is supplied at one end,

together with the requisite tobacco, and after passing through fourteen operations those materials are delivered at the other end in the shape of complete cigarettes.

##### (10.) Type Printing.

An excellent machine for founding type is exhibited in the Zollverein section by M. LEONHARDT, (58, p. 1050) by which 4,000 types can be made in an hour; and similar machines by Messrs. HOFFMANN (12, p. 1105) and BROCKHAUS (13, p. 1105), in Saxony, for founding and justifying type.

In the English part, Messrs. HARDING, PULLKIN, and JOHNSON (102, p. 280) exhibit the patent *approtypé* machinery, of which they are the proprietors. By this apparatus type is formed from copper, zinc, or other metals without heat, by means of dies and pressure, and is also dressed and regulated by the machinery.

The GUTTA PERCHA COMPANY of London (434, p. 301) contribute stereotype plates of gutta percha (with specimen impressions), in connexion with a large unfinished machine intended for printing therewith on endless paper, which is also to be cut and folded before it leaves the machine; the gutta percha types not requiring the paper to be damped.

Mr. COOKE (118, p. 280) shows a new arrangement of type-boxes for compositors; and M. SÖRENSEN, in the Danish section (13) exhibits an ingenious machine for composing and subsequently distributing type—this machine has not, however, had the advantage of experience.

Of printing-presses worked by hand, the following are exhibited:—By Messrs. COWSLADE and LOVEJOY (91, p. 279), with self-inking apparatus; by Messrs. SHENWIN, COPE, and CO (104, p. 280); by Messrs. E. and W. ULLMER (121, p. 280), also with self-inking apparatus; by Messrs. CLYMER and DIXON (124, p. 282); by Messrs. HOPKINSON and COPE (162, p. 285); and in model by Messrs. T. NELSON, jun. (120, p. 280), and COBB (150, p. 283).

Two forms of a hand printing-press, of novel arrangement and excellent workmanship, are exhibited by Messrs. RANSOMES and MAY (640, Class V., pp. 246, 247), one of which has a self-inking apparatus.

Cylinder printing machines are exhibited by Messrs. NAPIER and SON (158, p. 285); by Messrs. WATERLOW and SONS (164, p. 285); and in model by Mr. COWPER (134, pp. 282, 283).

The Scandinavian press of Messrs. HOPKINSON and COPE (162, p. 285) is worked by power, but has a vertical pressure.

In the great machine by Mr. APPELGATH, exhibited (122, pp. 280, 281) by Mr. INGRAM, by which the "Illustrated London News" is printed in the Exhibition, the printing cylinder is placed in a vertical direction. Four frames for supplying the paper are fixed in a radiating position from the centre, thus allowing four sheets to be printed in each turn of the cylinder.

Another printing machine, in which a stereotype plate is curved to fit the circumference of a cylinder, is exhibited by Mr. NELSON (120, p. 280).

##### (11.) Numbering, Paging, and Ruling Machines.

Messrs. CHURCH and GODDARD exhibit (135, p. 283) an elaborate machine, which prints, numbers, cuts, and packs railway tickets; and a smaller machine for numbering and printing tickets is shown by Messrs. HARRILL and SONS (157, p. 284). In the French division, Mr. HARANOWSKI (15, pp. 1171, 1172) has a neat and ingenious machine for the same and other purposes, in which the chance of error in the numbering apparatus is well provided against. Paging machines for ledgers, cheque-books, &c., are shown by Messrs. WATERLOW and SONS (164, p. 285), and by SCHLESINGER and CO. (Class XVII., 38, p. 589).

Machines for ruling paper are exhibited by Mr. SHAW (110, p. 280), and, in the French section, by M. RAUCHER-VERLINDO (413, p. 1195), the latter is arranged (in the manner of cylinder printing machines) so as to rule the paper on both sides before it quits the machine.

(12.) *Lithographic and Copper-plate Presses.*

In the English section the following Lithographic Presses are exhibited:—By Mr. SHAWWOOD (103, p. 280), in which a mangle wheel is used for producing the motion of the stone; by Messrs D. and J. GREIG (114, p. 280), with side lever and registering apparatus; by Mr. STRAKER (142, p. 283), with similar appendages; by Messrs. McCLOKE and Co. (160, p. 286), for a zinc plate, which is arranged over the leather cover; and by Mr. UNDERWOOD (473, Class V.), which is chiefly adapted for printing in colours. In the French section we also find a press, by Messrs. LACROIX and SON (283, p. 1190), and another by M. BAISSET (440, p. 1199), in which the top lever is turned sideways instead of being raised upwards as usual.

In the English section Messrs. D. and J. GREIG (114, p. 280) exhibit a copper-plate press, and Mr. FOURDUNNA a press (100, p. 280) to be worked by steam, and intended to print impressions, which are to be transferred to earthenware or china. This is accompanied by a specimen of his pottery tissue paper, in one continuous length of more than two miles and a half, manufactured from old coal-pit ropes and hawsers.

## (D.) WORKING PARTS OF MACHINES.

In all machines there are certain parts which actually do the work for which the machine is constructed, the mechanism serving merely to produce the proper relative motion of these parts to the material upon which they operate, and these working parts being the tools with which the machine operates.

Accordingly, in machinery for spinning and its preparatory processes, for weaving of all kinds, and for paper-making, there are a variety of such working tools, as, for example, spindles and flyers, fluted rollers, heckles, gills, all the variety of card-clothing for cotton, flax, wool, and silk, weavers' reeds and shuttles, the wire cloth employed by paper-makers, &c., the making of each of which articles constitutes a distinct branch, and is carried on by a different set of workmen from those who make the machines. For the machine-makers usually purchase these parts from their proper makers when they fit up their machines for sale, as the manufacturers and their workmen do when such parts are worn out.

Specimens of all these working parts have been transmitted to the Exhibition, and placed in Class VI.; although it might fairly be questioned whether they ought not rather to have been submitted to the judgment of the manufacturers, whose daily experience teaches them the qualities necessary to enable these working tools to perform their office well, and last the longest time—qualities which are quite independent of the merits of the machinery which sets them in motion; for as the best lathe will make bad work with a bad tool, so a good carding-engine, and a good loom, will fail, if fitted up with imperfect card-clothing, or ill-made reeds and shuttles; and reversely, the best tools are useless if attached to a bad machine. However, we may proceed to direct attention to the principal specimens of this kind, premising that many exhibitors have transmitted glass cases containing a few such articles that can be looked upon in no other light than as pattern-cards.

In the English Department we would select, for particular attention, the spindles of Mr. PRYOR (5, p. 268), the reeds of Mr. DE BRONX (45, p. 274); heckles by Mr. J. Taylor (61, p. 274); and a wool-comb by Mr. JOHN PERRY, of Bradford (suspended against the wool-combing machine of Mr. DOMESTON (40, p. 273)). Besides these there are others apparently very good, but so few of each as not to afford an equally good criterion of merit. In the French section Messrs. PAPAVOINE and CHATEL, of Rouen (339, p. 1193), the exhibitors of a machine for making card-clothing, already mentioned, also exhibit some samples of its work. Messrs. SCARVE BAOTRAS, of Lille (1603, p. 1227), contribute excellent samples of card-clothing for cotton and wool, some having the teeth set in leather, others in Horsfall's patent card-cloth. Messrs. MIXOUX BAOTRAS, of Rouen (645, p.

1207), also send excellent specimens of cards for cotton, tow, silk, and wool. Mr. HARDING COCKER, of Lille (864, p. 1221), furnishes a large number of capital heckles, gills, porcupines, and combs. Messrs. DANDOT, MAILLARD, LUCC, and Co., of Maubeuge (491, p. 1201), exhibit well-made spindles, rollers, bolsters, steps, &c. Many other exhibitors in this class are to be found in France, Belgium, Spain, Switzerland, and the Zollverein. Some reeds, by Madame CUYERE, from Tuscany (72, p. 1296), merit notice.

## (E.) ENGINEERS' TOOLS FOR METAL, WOOD, AND OTHER MATERIALS.

13. *Lathes.*

Amongst the machine tools, lathes, as might be expected, appear in the greatest number and of every variety of size and arrangement, from the powerful machines, which are capable of turning wheels of 8 feet in diameter, or shafts 36 feet in length, down to the delicate lathes used by amateurs, or the makers of small machines and apparatus. However, it must be remarked, that in this collection, complete as it is, several important machines are not represented, as, for example, the colossal lathes which are employed for boring cylinders.

A magnificent railway-wheel lathe, with two opposite headstocks and face plates, and two compound slide-rests to correspond, capable of turning wheels above seven feet in diameter, is exhibited by Messrs. SHARP (204, p. 291), and one of smaller dimensions by Messrs. WHITWORTH and Co. (201, pp. 287-90), who also contribute two of their patent duplex lathes, in which the work is acted upon simultaneously by two tools cutting at the opposite extremities of the same horizontal diametrical line. Thus vibration and deviation of the work in shaft turning is wholly prevented. The beds of these lathes are 18 feet and 36 feet in length respectively, and the latter is provided with two duplex slide-rests, which can be made to travel simultaneously by self-action, either in the same or opposite directions at pleasure, so as to economize the time required for finishing the work. They also exhibit a 5-inch self-acting foot-lathe, with complete arrangements for sliding, screwing, and surfacing. Large lathes of excellent workmanship, each having some peculiar facilities in the details, and adapted for sliding, screwing, and surfacing by self-action, are exhibited by Messrs. SMITH, BEACOCK, and TANNITT (230, p. 295), PARR, CURTIS, and MADELEY (213, p. 292), SANDFORD, OWEN, and WATSON (223, p. 294), and SHEPHERD, HALL, and SITSK (220, p. 293). Mr. MITT (206, p. 291-2), contributes a well-made small foot lathe, with a variety of screw stocks and other tools.

In the American Department, a lathe sent by the LOWELL MACHINE SHOP (447, p. 1464), of 12-inch centre and 13-foot bed, with the usual arrangements for self-action, will be looked on with great interest, as a specimen of first-rate transatlantic workmanship in this branch, and as offering various peculiarities of form and distribution of metal, the latter being employed as sparingly as possible on account of the great cost of iron. Hence a lightness of construction carried to the extreme point consistent with strength and stiffness, which presents a singular contrast to the solid proportions adopted by our own engineers.

In the smaller class of lathes Messrs. HOLTZAPFEL and Co. (232, p. 295) take the lead, by exhibiting a first-rate amateur lathe, provided with all the apparatus required for ornamental turning, such as oval, eccentric, and drilled work, and a variety of tools and contrivances appertaining thereto, of the most elegant and perfect workmanship. Mr. DALGETY (226, p. 294), has a highly-finished lathe, to which is appended, amongst other things, his useful chuck, which is capable of fixing perfectly central a wire of any size not larger than 4-inch. Other lathes are contributed by Mr. WILLIAMS (234, p. 295), with a new tool-holder and self-acting screw cutting apparatus; by the Messrs. KNIGHT (614), who have fitted up a complete amateur-work cabinet, and by Messrs. FADES and SON (224, p. 294). Messrs. MORRAN, SANFORD and Co. (205, p. 291), send a new machine for

tracing rose-engine patterns, M. KAMANN (Prussia, 58, p. 1052) has a highly-finished amateur lathe, adapted for turning either in metal, or wood and ivory, and provided with a variety of the usual chucks and apparatus.

#### (14.) Planing Machines.

Six planing machines are to be found in the collection, amongst which, of course, those of the largest size are not sent, on account of their bulk and weight, and because their arrangements are the same as those of the medium size, of which excellent specimens are exhibited by Messrs. SHARP (204, p. 291), PARR and Co. (213, p. 292), and Messrs. WHITWORTH (201, pp. 287-290), the latter sending two, of which one is provided with his revolving reversing tool, which enables the machine to plane both ways. The varieties of construction by which these admirable machines are individually distinguished, although they are perfectly similar in general form and purpose, afford the most interesting studies for the engineer and mechanist. This remark may be applied with equal force to the slotting and shaping engines about to be described, and indeed to many other groups of machines in the present collection. Messrs. WHITWORTH also send a small planing machine (two feet six inches long) moved by a crank, arranged to give a slow cutting action and a quick return; and Mr. SHANKS (210) a diminutive hand-machine for the use of opticians.

#### (15.) Slotting Machines.

Of slotting and paring machines we find one large specimen from Messrs. SHARP (204, p. 291), and two smaller ones by Messrs. WHITWORTH, (201, pp. 287-290). One of the latter is provided with a complex bed for sustaining the work, composed of four rectilinear slides, and one rotating disk, by means of which any form composed of a combination of excentric circular arcs, and straight lines, may be pared and finished upon the machine.

#### (16.) Shaping Machines.

The shaping machine, as it is called, is a kind of planing machine in which the tool is attached by proper slides and holders to the end of a horizontal bar, to which a reciprocating motion for cutting is communicated in the direction of its length, by a crank or excentric. The work is either fixed to a horizontal table with longitudinal and vertical adjustments, or to an arbour, and the machine is employed for shaping levers and cranks or curved and plane forms in general, and as it is susceptible of many varieties of construction and detail; the six specimens which are here exhibited by several leading engineers will be compared with great interest by mechanists. The largest is contributed by Messrs. PARR (213, p. 292), in which the tool has a stroke of twelve inches, and the bed is seven feet long; two lesser ones are sent by Messrs. SMITH, BEACOCK, & Co. (230, p. 295), and one by Messrs. WHITWORTH (201, pp. 287-290). Messrs. SHARP (p. 291) exhibit one of a very neat and compact arrangement, but not possessing all the capabilities of those just mentioned, and there is also one sent by Mr. SHANKS (210, p. 292).

#### (17.) Drilling and Boring Machines.

There are six drilling machines of various sizes and capabilities; amongst them Messrs. WHITWORTH again appear, as the exhibitors of a large radial drill, the framing of which may be selected as an admirable specimen of casting in iron. The arm of this machine is movable through an arc of 190°. Messrs. HICK (218, pp. 292, 298) contribute a large radial drilling machine, the pillar of which is formed into a screw that allows the arm to be turned completely round, and raised to any required altitude.

Excellent self-acting vertical drilling and boring machines, with various arrangements of the table, are exhibited by Messrs. WHITWORTH (201), SMITH & Co. (230, p. 295), PARR & Co. (213, p. 292), and WILLIAMS (234, p. 294).

#### (18.) Other Machine Tools for Metals.

The remaining specimens of machine tools may be enumerated as follows:

Engines for wheel-cutting and dividing by Messrs. WHITWORTH (201, pp. 287-90), and LEWIS and SONS (209, p. 293); a small machine for forming circular cutters by Messrs. SMITH (230, p. 295); bolt-screwing machines by Messrs. WHITWORTH (201), GLASGOW (210, p. 293), and SHANKS (210, p. 292); a bolt-head and nut-shaping machine, with two machines for punching and shearing, by Messrs. WHITWORTH (201, *at supra*).

From the above description of engineers' tools, it will be seen that Mr. WHITWORTH has contributed one or more specimens of first-rate excellence under each head. In addition it is necessary to direct particular attention to his measuring machine (which, however, properly belongs to the Class of Philosophical Instruments), and to the admirable collection of apparatus, by the employment of which a uniformity of system in the dimensions and fitting of machinery, and in the sizes and arrangements of screw-threads, is rendered practicable amongst engineers in general. The confusion and delay occasioned in the repair of machinery and apparatus of all kinds by the want of such a system have long been felt; and the attention of engineers was directed to the subject by a paper communicated to the Institution of Civil Engineers in 1841, by Mr. Whitworth. His system has already obtained great extension, and he has contributed to the present Exhibition a complete set of the apparatus required to carry it out. This includes different sizes of guide-stocks, and the several dies, taps, &c., for producing the corresponding screws which he has selected as the standard forms of his system, and also sets of standard gauges, by the use of which corresponding parts of machines may be prepared separately, with sufficient accuracy to fit without trial. He also exhibits specimens of surface-plates, prepared without grinding, according to the method described in his paper (read at the meeting of the British Association in 1850).

In the American Department, Mr. DICK (79, p. 1438) exhibits a variety of powerful machines for producing pressure with small friction, by means of a peculiar combination of levers whose surfaces act by rolling contact, and which are formed into curves that enable them either to produce a constant or a varying pressure according to the nature of the machine. One of these is arranged to act as a boiler-plate shearing and punching machine. Messrs. FAIRBAIN and SONS (200, pp. 286, 287) contribute their important and original machine for rivetting boiler-plates by pressure; and Messrs. W. J. and J. GARFORTH (208, p. 292) an improved machine for the same purpose, in which the pressure is produced by the direct action of the piston rod of a steam cylinder.

The admirable steam hammer of Messrs. NASMYTH and Co. (236, p. 295) is too well known to require any lengthened notice in this place. It is only to be regretted that the nature of its operations forbids it to be put in action in the Exhibition. The effective and useful forging machine of Mr. RYDER (222, p. 294) is, however, shown in motion, its action being exhibited upon rods of lead.

In the French Department, M. SCHWENGER (1475, p. 1246) has placed a forging machine in which the hammer is raised and thrown up by a cam; piles of vulcanized quenching are employed to diminish the shock to the cam, and also to produce a rebounding blow.

Two large ceiling presses are placed in the Exhibition, the one by Messrs. MAUDSLAY, SONS, and FIELD (228, p. 294); the other (in the Zollverein Department), by M. UHLHORN (476, p. 4078). In each, the screw is dispensed with, and they may be considered as examples of the best style of design and workmanship by which their respective countries are characterized.

Mr. MORRALL, of Studley (240, p. 295), maintains, in action, a series of the simple apparatus employed in making needles, especially those which he terms "grooveless needles," of his own invention.

There is an abundance of small fly-presses in the building. Mr. MANSELL (502, p. 305) has one with peculiar

arrangements for cutting on an even surface of steel, without injuring the tools; and in the Swiss Department M. DARIEN (Switz., 61, p. 1270), exhibits a press with many delicate adjustments for cutting watch-hands. The remainder of these presses are of a highly ornamental character, and intended for the library table, or shop counter, as copying-presses, or for seals, book-stamps, &c., and in this character they properly belong to "ornamental furniture," or "stationery," as their chief claim to attention consists in the beauty of their form or decoration.

In the Foreign Department we may mention a highly-finished rolling-mill, of most accurate workmanship, adapted for a mint, by M. KATFF (Prussia, 649, p. 1086); an excellent machine, for forming hooks and eyes, by M. HUE (France, 269, p. 1189); and three ingenious machines, of very similar construction, for making the nails called "points de Paris," of which one is exhibited by M. FREY (1607, p. 1254), the other two by M. STOLTZ (1494, p. 1248).

Messrs. R. JOHNSON and BROTHERS, of Manchester (312, p. 292), have placed in the collection a wire-drawing bench of the best construction, being the only machine for this purpose that has been forwarded.

Mr. FELIX ABATE exhibits in Class XXII., (265, p. 623) some machines intended for planing, polishing, burnishing, and ornamenting sheets, bars, tubes, &c., of metal.

Messrs. VINE and ASHMEAD contribute, from America (196, p. 1449), a gold-beating machine.

Messrs. STEWART and Co. (238, p. 295) exhibit a model of their machine for forming the moulds in which iron pipes are cast. Several excellent specimens of large pipes, that accompany the model, show the perfection which the machine imparts to the mould, and the machine itself would have been sent, but it was found to be too large for the building.

• An elaborate machine, for making and charging percussion caps, is exhibited in the Department of the Netherlands, by Mr. GOOSSEKES (77, p. 1116). This machine, which is worked by two men and three children, does the work (according to the inventor's statement) of twelve machines and twenty-five men required in the system commonly employed.

#### (19.) *Machines for Working in Wood (excepting Lathes.)*

From the above sketch it will be seen that the Exhibition presents a tolerably fair picture of the present style of English engineer tool-making for metal-work, and that very few specimens have been sent either from the Continent or from America. When we turn to the machines for working in wood the case is altered. It certainly cannot be said that such machines are not employed in England; for, from the period of setting up the Portsmouth block-machinery, such contrivances have been gradually making their way into English practice, and our saw-mills, dockyards, and similar establishments, abound with mechanism for sawing, veneering, planing, grooving, mortising, tonguing, cutting mouldings, cask-making, carving, and every branch of wood-work: but, from some cause or other, probably the magnitude or roughness of such mechanism, and the noise, chips, and dust it creates, only a few models have found their way into the English Department of the Exhibition; nevertheless, the wood-work of the very building in which they are contained was itself almost entirely wrought into form by such machines. In America, however, machinery for working in wood is even more largely employed than with us, and their machines find their way into workshops of a smaller character. The much greater value of manual labour in that country is shown by the fact, that as little work as possible is done by hand, and that more attention is paid to economy of time and labour, and to the production of rapid results with the least possible expenditure, than to great durability and finish. Where so many natural obstacles are to be contended against by a scattered population, we must not look so much for elegance of workmanship as for boldness of design. These remarks are illustrated by a series of machines for working in wood, which, although exhibited in

operation by the English importer and patentee, Mr. FURNESS, of Liverpool (471, p. 298), are of American origin, and some of them are well known to have been largely employed there for ten years or more. The style of framing and designing these machines will at once betray their Transatlantic origin, and exhibits great ingenuity, simplicity, and fitness for the purpose. They are principally framed of wood, not only for cheapness, but because iron frames are liable to bruise the highly-finished wood-work which the machines are intended to produce. This series comprises a most effective foot-mortising machine; a tenoning machine, to be worked by hand or power; and power-machines for mortising, planing, moulding, and sash-making. Mr. WOODBURY, of the United States (443, pp. 1463, 1464), exhibits a powerful machine for wood-planing, tonguing, and grooving rough boards of 2 feet, or less, in width. The boards are driven under a series of eight fixed cutters or plane-irons, each cutting in succession, and may be planed at the rate of 90 feet per minute. A working model of an effective machine for dressing the staves of casks, patented by Messrs. WELLS and THOMPSON, of America, was placed among the English machines in motion, after the dispersion of the Jury.

In the French Department, Mr. SATTREUIL (1-3, p. 1246), contributes a powerful planing and moulding machine, in which revolving cutters are employed, with some important improvements in their form and mode of action.

In the English Department, Mr. BIRCH (406, p. 299), exhibits a model of the machine by which the sash-bars of the Exhibition building were entirely formed at a single operation, as described in the Illustrated Catalogue; and Mr. BARKER (417, p. 201) shows models of his machinery for curvilinear sawing of ship timbers (patented in 1845). An American machine, for the same purpose, by Mr. COCHRAN (patented in 1847), is also exhibited in model (United States, 297, p. 1453). Messrs. PROSSER and HODLEY (456, p. 304) have a large and well-made buhl sawing machine, capable of executing pierced work for furniture on a large scale; and Mr. COATS (25, p. 271) a machine for the rapid manufacture of bobbins. In the Belgian Department (472, p. 1166) Mr. WYNANTS exhibits a small machine for carving in wood. Although not placed in our department, we may be permitted to mention Mr. BERNEL's apparatus (Class IX., 37), by which a framed hurdle may be completely constructed by one man in twelve minutes.

#### (20.) *Working in Stone, Coal, Clay, Leather, &c.*

**Stone.** Mr. HUNTER (312, p. 297) exhibits a model of his well-known stone-planing machine, which has been so long and effectually employed in Scotland and elsewhere. Messrs. RANDELL and SAUNDERS (324) have sent several models of stone-sawing machines, which they have in operation in quarries at Corsham, near Bath: one of them is employed for cutting the stone from its natural rock in the quarry itself. It works eight saws, 24 feet long in the original.

A machine for dressing or shaping stone, by Mr. EASTMAN, of the United States (460, p. 1464), is exhibited, in action, amongst the English machinery in motion. In this engine, rolling cutters of chilled cast iron are employed, which crush and rapidly wear away, in the form of scale and dust, the granite, sandstone, marble, millstone, or other material which is subjected to their action. Mr. COCHRAN, United States (297, p. 1453), also exhibits a model of a machine for stone planing.

**Coal.**—Two machines, with revolving cutter-wheels, intended for cutting coal, are shown by Mr. WARRING (305, p. 205), one to cut in vertical planes, the other in a horizontal plane.

**Glass.**—Messrs. CLAUDET and HOUGHTON (306, p. 295) exhibit two neat contrivances for cutting and trimming glass shades to any required height.

**Lather.**—In the French Department Messrs. DUMAS (487, p. 1201) exhibit a collection of specimens of boots and shoes in which soles are employed in lieu of stitches, and some of the machines which they use for blocking

boots, cutting-out soles, &c. These machines, however, are not completely fitted up.

In the English section Mr. MANLY (502, p. 305) has a boot-blocking machine; and Mr. VAIT (504, p. 305) a kind of printing machine, intended to print the outlines of the parts of shoes or boots upon cloth or leather, as a guide to the cutter-out.

M. SENECHAL, France (373, p. 1194), has a press for cutting-out gloves.

**Clay.**—The Exhibition contains twelve or fourteen brick and tile machines of various kinds, most of which have been placed in the "Agricultural Department," which is their proper location—agricultural gentlemen being usually qualified by practice and experience to judge of the performance of such machines. Of the few that have accidentally found their way into Class VI. we may mention Mr. BEART's machines for making hollow bricks (301, p. 295), and a machine of Messrs. RANDIEL and SAUNDERS (324, p. 297), in which the clay is forced through the mould by the continuous action of two revolving spirals instead of the usual reciprocating piston.

In the French Department, Messrs. HORIE BROTHERS (417, p. 1198) exhibit an excellent machine for making hollow bricks, in which the plugs of the mould are supported with great skill, in such a manner as to obviate the splitting of the bricks, which, in the common construction, is apt to result from the position of the bridges by which the plugs are carried.

#### (F.) GRINDING AND CLEANING FLOUR AND OTHER VIGILABLE PRODUCTS.

##### (21.) Mills for Grinding.

In the first place we may direct attention to the stones, steel, and iron plates, &c., by which the grain or other material is to be crushed; many specimens of these are exhibited, detached from the machines by which they must be maintained in motion when used.

Messrs. TONS and Co. (457, p. 304) exhibit French millstones made at La Ferme-sous-Jouarre, and fitted with Hanon-valck's patent scraper, for introducing fresh air between the stones.

Messrs. HUGGINS and SONS (459, p. 304) have also a pair of stones with channels for the introduction of air, and Mr. CLAYTON (440) a pair of French stones.

Mr. HURWOOD (414, p. 301) specimens of grinding plates in steel and cast iron formed in concentric rings.

In the French section, burr-stones of different sorts and qualities are exhibited by GAILLARD, SON (226, p. 1187), PETIT and Co. (345, p. 1194), BOUCHON (431, p. 1199), GUYEN-BOUCHON and Co. (532, p. 1204), MONTCHARNONT (650, p. 1209), ROGIER (1448, p. 1245), TRUBAUT BOULEVE (1502, p. 1218), TOUAILLON (1508, p. 1248); and in the Zollverein section, M. LANDAU (321, p. 1069), stones of lava quarried near the Moselle.

Mills, fitted up for grinding grain, ore, &c., are shown under the following numbers: Messrs. FAIRBANKS (405, p. 298) a corn-mill on a cast-iron frame with gearing showing their improvements in the modes of driving, adjusting, and feeding the mill-stones.

Messrs. CONCORAN and Co. (416, p. 301) a portable corn-mill with French burr-stone intended for the use of emigrants; and Messrs. TOOTH (4167) a small hand-mill.

Mr. BOURCHON (France, 431, p. 1199) also exhibits a small mill complete with bolting machine, for emigrants.

Messrs. WEAVER and Co. (442, p. 303) a mill of a peculiar and compact arrangement, consisting of two pairs of conical stones, one above the other, but attached to the same spindle; between them is a conical wire sieve, with brushes fixed to the spindle, by which the fine flour detached by the upper stones is separated from the grain before the coarser parts fall to the lower stones.

In the American section, Mr. ROSS (413, p. 1450), a model of a portable mill.

Messrs. MERRILL and CARTER (France, 635, p. 1208) exhibit a small portable mill complete, in which the lower

stone is the runner, and there is an arrangement for the introduction of atmospheric air between the stones.

In the Belgian section M. HOUYER (125, p. 1155), and M. DANNEAU (431, p. 1155), exhibit each a model of a small mill, with a ventilator to drive atmospheric air between the grinding surfaces.

A little machine to enable a workman to cut and sharpen mill-stones with great precision, and without danger to his eyes from chips, is exhibited in the English section by Mr. PARSONS (Class V. 642, p. 247); and in the French section a similar contrivance by M. TOUAILLON (1508, p. 1248).

Mr. CROSSKILL (404, pp. 298, 299), Mr. HURWOOD (414, p. 301), and Messrs. S. and C. ADAMS (429, p. 302) have exhibited a variety of mills fitted with metal plates for grinding wheat and other vegetable substances, bones, minerals, &c.

Coffee-mills are shown by W. MUIR (306, pp. 291, 292), FIELDHOUSE and Co. (443, p. 303), SAVAGE (458, p. 304), and VANDENBROUCKE (France, 711, p. 1230). A handsome silver apparatus for roasting coffee is exhibited by Messrs. DAKIN and Co. (408, pp. 299, 300).

In the French section M. HERMANN (873, p. 1221) has fitted up a complete and admirable set of machines largely employed for the manufacture of chocolate, by which the cocoa beans are crushed after being roasted, mixed with sugar, and the chocolate fully prepared for use. Also an apparatus for mixing and grinding greasy matters for perfumes, soaps, &c. A mixing machine for chocolate is also exhibited by Messrs. GATTI and BOUTY (450, p. 303); and a set of excellent machinery for crushing and grinding potatoes, and for making potato flour by a cylinder with saw blades, by M. HUCK (France, 511, p. 1204).

##### (22.) Machines for Cleaning and Separating the Products.

We will now proceed to enumerate the machines for cleaning grain and separating the finer particles from the coarser after grinding, for which a variety of arrangements are shown, differing in the position of the revolving sieves, in the material and disposition of the brushes and beaters, and in other particulars.

Mr. HUNT (422, p. 301), vertical flour-dressing machine, with hair brushes.

Mr. HEDFORD (426, p. 302), inclined wire cylinder, with external revolving hair brushes.

Mr. BLACKMORE (128, p. 302), model of a bolting machine, having cloths without seams and revolving gutta percha flaps outside for cleaning the cloth.

Mr. SPILLER (436, p. 302), flour-dressing machine; Mr. SHORE (438, p. 302), flour-dressing machine, with cylindrical wire sieves, having revolving wings inside, with steel plates in lieu of brushes; Messrs. COOMBS and Co. (444, p. 303), models of inclined and vertical cleaning and dressing machines; Mr. WEATHERLEY (441, p. 302), a small machine for cleaning currants, with whalebone brushes; Messrs. H. and E. MILLINGTON (462, p. 305), a cleaning, or smut machine, with revolving wire brushes; Messrs. R. and J. HANKIN (466, p. 305), a vertical smut machine, having an exhaustor above to remove the dust; and, finally, Mr. ASHBY (470, p. 305), an upright flour-dressing machine.

In the French section, machines are exhibited by M. HUCK (541, p. 1204), for extracting and separating flour from ground potatoes; Messrs. VACHON and Co. (705, p. 1212), for cleaning grain; and M. HENNECART (1266, p. 1237), for bolting flour, having a silk cover, and accompanied by various excellent specimens of silk gauze for bolting.

In the Belgian section we find machines for cleaning and glazing rice, by M. HOUYER (125, p. 1155); and a cylindrical machine for cleaning grain, by M. DANNEAU (507, p. 1167).

Under the present head may be mentioned a set of effective machines by Messrs. BARNETT and Co., of Reading (410, p. 301), for manufacturing biscuits. In the French section an elegant machine for kneading dough by means of a revolving spiral, by M. BOZARD (423, p. 1199). A model of a machine for making biscuits,

termed "Cribberson's cracker machine," was placed in the American Department after the Jury had concluded their labours.

Other machines, for similar purposes with the above, are placed in the class of Agricultural Implements, and have therefore not been submitted to our inspection. Indeed, it may fairly be questioned whether the greater part of those already enumerated might not have been also placed in Class IX. with advantage.

#### (G). MANUFACTURE OF SUGAR.

The sugar-cane mill of Messrs. ROBINSONS and RUSSELL (418, p. 301), a magnificent specimen of mill-work on the largest scale, with horizontal cylinders, is shown in partial action. Messrs. COLLINGS and Co. (432, p. 302) also exhibit a horizontal sugar mill, and Messrs. GRAHAM, WEST and Co. (445, p. 303) several beautifully constructed models of different forms of sugar mills, &c.

Three superb sets of vacuum apparatus, for the manufacture of sugar, are exhibited; each from a different country, and each remarkable for magnitude, perfection of workmanship, and excellence of arrangement, as well as for peculiarities characteristic of the nations that have produced them. The English machine of Messrs. PONTIFEX and WOOD (602, p. 305) is of great manufacturing power; and its enormous dome, formed from a single piece of copper, is a very wonderful specimen of the coppersmith's art. The French machine, by Messrs. CAIL and Co. (1557, p. 1251), is similar in its general form and magnitude, of admirable workmanship, and considered by French practical chemists to be even superior in its arrangements to that of Messrs. PONTIFEX. The machine of M. HECKMANN (Prussia, 52, p. 1050, and see 'Illustrated' 1051), although not equal in magnitude, nor perhaps in workmanship, to the two already mentioned, must be regarded as a contribution of first-rate merit.

The hydro-extractor or revolving machine, by which water is driven out of goods by centrifugal force, was invented by Mr. SEYRIG many years since, and its great merit, utility, and economy, have been the means of extending it throughout the manufacturing world. Its application to the separation of sugar from molasses was the subsequent suggestion of another party. Several specimens of this engine are exhibited, of various degrees

of merit, of which we may mention those of the original inventors and proprietors, Messrs. MANLOVE, ALLIOTT, and SEYRIG (454, pp. 303, 304); a well-made machine by Mr. BESSEMER (400, p. 297, 298); and one by Messrs. RITCH and FINZEL (405, p. 299). In the French Department, one by Messrs. BEZAULT and Co. (425, p. 1199); and in the Belgian, one by Mr. VANGOTHEM (124, p. 1155).

#### (H). APPARATUS FOR BREWING, DISTILLING, AND MANUFACTURING CHEMISTRY.

Mr. LAWRENCE's distributor (604, p. 305) has the advantage of an equal distribution of heat throughout the wash, either by steam or water, and facility of cleansing the false bottom. He also exhibits a good refrigerator and a store cask, for preserving beer in store, and preventing accidents in bursting. Mr. TIZZARD (630, p. 307) has a model of a brewery, exhibiting several novel and useful arrangements of the backs, mash tun, refrigerator, fermenting and cleansing tuns, and employing steam for heating the liquor back, &c. Mr. WHEELER's refrigerator, exhibited by Mr. HULLS (618, p. 307), is said to be very rapid in its action. Refrigerators are also sent by Messrs. ASKEW (611, p. 307), COFFEY (615, p. 307), and THOMSON, YOUNGER and Co. (623, p. 307). Carbonating or aerating machines, for making soda water, Seltzer water, &c., are exhibited by Messrs. COXE (608, p. 307), in which pumps may be employed to exhaust the atmospheric air from the water, previously to carbonizing it, or to force the carbonic gas into the water, when so deprived of the common air. Other machines are exhibited by Messrs. TYLER and Co. (605, p. 306), and by Messrs. COOPER and BURNELL (624, p. 307).

Of apparatus for other chemical manufactures we may direct particular attention to BOTTRA's colour extractor, (610, p. 307); DAWSON's new distillers' and rectifiers' recording close safe (612, p. 307), for the Excise; HAL-LIDAY's apparatus for the manufacture of pyroligneous acid (617, p. 307); and HILL, EVAN, and Co.'s patent vinegar apparatus (614, p. 307).

As partly connected with the above subjects may be mentioned J. and T. MASTERMAN's apparatus for corking bottles (621, p. 307); and in the French Department (651, p. 1209), a machine for the same purpose, by the Marquis ALFRED DE MONTECELLO.

### AWARDS, CLASS VI.

#### THE COUNCIL MEDAL.

| Nation.        | Number in Catalogue. | Names of Exhibitors.      | Objects Rewarded.  |

| United Kingdom | 82                   | Barlow, A.                | Double-action Jacquard Loom.                                       |
| France         | 1557                 | Call and Co.              | Vacuum Sugar Apparatus.  |
| United Kingdom | 40                   | Donisthorpe, G. E.        | Wool-combing Machinery.  |
| United Kingdom | 130                  | Donkin, B., and Co.       | Paper-making Machinery.  |
| United States  | 79                   | Dick, D.                  | Antifriction Engineers' Tools and Presses.                         |
| United Kingdom | 200 & 403            | Fairbairn, W., and Sons   | Rivetting Machine and Corn Mill.                                   |
| France         | 873                  | Hermann, G.               | Chocolate-making Machinery.  |
| United Kingdom | 218                  | Hick, B., and Son         | Mill Gearing, Radial Drill Mandrills, and Portable Forges.         |
| Prussia        | 52                   | Heckmann, C.              | Vacuum Sugar Apparatus.  |
| United Kingdom | 1                    | Hibbert, Platt, and Sons  | Cotton Machinery.  |
| Prussia        | 649                  | Krupp, F.                 | Flattening Rollers (Awarded also by Class I.)                      |
| United Kingdom | 75                   | Lawson, S., and Sons      | Flax Machinery.  |
| United Kingdom | 10 & 46              | Mason, J.                 | Cotton and Woollen Machinery.                                      |
| United Kingdom | 228                  | Maudslay, Sons, and Field | Coining Press.   |
| France         | 632                  | Mercler, A. and Co.       | Woollen Machinery.   |
| United Kingdom | 236                  | Nasmyth, J.               | Steam Hammer.  |
| United Kingdom | 77                   | Parker, C. E., and Co.    | Sailcloth Power Loom.  |
| United Kingdom | 602                  | Pontifex and Wood         | Vacuum Sugar Apparatus.  |
| United Kingdom | 85                   | Reed, T. S., and Co.      | Fringe Power Loom.   |
| France         | 1438                 | Risler, G. A.             | Epurateur for Cotton.  |
| United Kingdom | 204                  | Sharp Brothers and Co.    | Engineers' Machine Tools, and Throstle.                            |
| Prussia        | 476                  | Uhlhorn, H.               | Coining Press.   |
| United Kingdom | 201                  | Whitworth, J., and Co.    | Engineers' Machine Tools, Measuring Machine, Knitting Machine, &c. |

## THE PRIZE MEDAL.

| Nation.        | Number in Catalogue. | Names of Exhibitors.            | Objects Rewarded.   |
|----------------|----------------------|---------------------------------|---|
| France         | 399                  | Aeklin                          | Jacquard, employing paper instead of cards.   |
| United Kingdom | 448                  | Adorno, J. N.                   | Cigarette Machine.  |
| United Kingdom | 10                   | Ball, Dnnielcliff, and Co.      | Warp Lace Machine.  |
| United Kingdom | 48                   | Berry, B. and Sons              | Various Machinery for manufacturing Worsted.  |
| France         | 422                  | Berthelot, N.                   | Circular Hosiery Frames.  |
| United Kingdom | 400                  | Besemer, H.                     | Centrifugal Machine for separating Molasses.  |
| United Kingdom | 406                  | Biroh, J.                       | Machine for cutting Sash-bars.  |
| United Kingdom | 94                   | Birkin, R.                      | Bobbin-net-Lace Machine, with Jacquard.   |
| United Kingdom | 138                  | Black, J.                       | Folding Machine.  |
| United States  | 551                  | Blodget, S. C.                  | Sewing Machine.   |
| France         | 428                  | Boland, A.                      | Kneading Machine.   |
| Prussia        | 53                   | Bonardel Brothers               | Jacquard, and Punching Machine for Jacquard Cards.  |
| France         | 417                  | Borie Brothers                  | Brickmaking Machine for Hollow Bricks.  |
| France         | 15                   | Baranowski, J. J.               | Machine for Printing and Numbering Tickets.   |
| United Kingdom | 144                  | Brewer, C. and W.               | Rollers of Wire Cloth for Paper-makers.   |
| United Kingdom | 27                   | Calver, F. A.                   | Wool-burring and Cotton-cleaning Machines and Cylinders.  |
| United Kingdom | 135                  | Church and Goddard              | Machine for Cutting Cardboards, and Printing and Preparing Railway Tickets.                                       |
| United Kingdom | 86                   | Claussen, P.                    | Circular Hand-loom for Hosiery.   |
| United Kingdom | 78                   | Crawhall, J.                    | Machine for manufacturing Ropes.  |
| United Kingdom | 35                   | Crichton, D.                    | New Taking-up Motion for a Loom.  |
| Tuscany        | 59                   | Cuyere, Mrs.                    | Weavers' Reeds.   |
| United Kingdom | 80                   | Davenport, J. L.                | Various Machines for manufacturing Silk.  |
| United Kingdom | 226                  | Dalgaty, A.                     | Small Lathe, with Self-adjusting Chuck.   |
| United Kingdom | 45                   | De Bèrgue, C.                   | Reels made by Machinery.  |
| United Kingdom | 76                   | De la Rue and Co. (Class XVII.) | Machine for folding and gumming Envelopes.  |
| France         | 491                  | Dandoy-Mailliard, Lucq, and Co. | Rollers for Spinning Machinery.   |
| Switzerland    | 61                   | Darior, H.                      | Press for cutting-out Watch Hands.  |
| France         | 823                  | Dorey, J. F.                    | Machine for weaving improved Healds.  |
| United States  | 456                  | Earle, T. K., and Co.           | Card Clothing.  |
| France         | 1607                 | Frey, jun.                      | Machine for making nails.   |
| United Kingdom | 84                   | Frost, Jc                       | Improved silk Machinery.  |
| United Kingdom | 401                  | Furness, W.                     | Machines for working in wood.   |
| Austria        | 109                  | Gamba, P., the Heirs of         | Jacquard Cylinder.  |
| United Kingdom | 208                  | Garforth, W. J. and J.          | Steam Rivetting Machine.  |
| Prussia        | 58                   | Hamann, A.                      | Turning Lathe.  |
| United Kingdom | 102                  | Harding, Pullcin, and Johnson   | Machinery for making Printing Type.   |
| France         | 864                  | Harding-Cocker                  | Heckles.  |
| United States  | 386                  | Hayden, W.                      | Drawing Regulator for Cotton.   |
| United Kingdom | 14                   | Higgins and Sons                | Cotton Machinery, and Long Line Flax Machinery.   |
| United Kingdom | 232                  | Holtzapffel and Co.             | Amateur Foot Lathe, with various Apparatus and Tools.   |
| United Kingdom | 20                   | Hornby and Kenworthy            | Sizing and Dressing Machine, and Self-acting Backing-off Motion to a Warping Machine.                             |
| France         | 541                  | Huck                            | Apparatus for grinding and preparing Potatoes, &c.  |
| France         | 269                  | Hue, J. B.                      | Press for Bending and Cutting Hooks and Eyes.   |
| United Kingdom | 122                  | Ingram, H.                      | Applegath's Vertical Printing Machine.  |
| France         | 546                  | Jacquin, J. J.                  | Circular Hosiery Frames.  |
| United Kingdom | 212                  | Johnson, R., and Brothers       | Wire-drawing Benches.   |
| United Kingdom | 52                   | Judkins, C. T.                  | Heald Machine, and improved Heald.  |
| United Kingdom | 21                   | Kenworthy and Bullough          | Stopping Motions to a Power Loom.   |
| United Kingdom | 604                  | Lawrence, J. sen.               | Refrigerator, Store Cask, &c.   |
| France         | 283                  | Lacroix and Son                 | Fulling Machine for Cloth.  |
| Prussia        | 55                   | Leonhardt, J. E.                | Type-founding Machine.  |
| United Kingdom | 209                  | Lewis, F., and Sons             | Wheel-cutting Engine and Roving Spindle.  |
| United States  | 447                  | Lowell Machine Shop             | Self-acting Lathe and Power Loom.   |
| United Kingdom | 454                  | Manlove, Allott, and Seyrig     | Centrifugal Washing and Drying Machine.   |
| United Kingdom | 206                  | Muir, W.                        | Small Lathe and various Tools.  |
| France         | 330                  | Mareschal, J.                   | Machine for Mining Meat.  |
| France         | 645                  | Miroude Brothers                | Card Clothing.  |
| United States  | 460                  | Morey, C.                       | Eastman's Stone-cutting Machines.   |
| France         | 664                  | Nicolas, P.                     | Machine for Engraving Cylinders.  |
| United Kingdom | 158                  | Napier and Son                  | Letter-press Printing Machinery.  |
| United Kingdom | 40                   | Perry, John                     | Wool-comb.  |
| United Kingdom | 5                    | Reston, F.                      | Spindles and Flyers.  |
| United Kingdom | 456                  | Prosser and Hadley              | Ornamental Sawing Machine.  |
| United Kingdom | 74                   | Plummer, R.                     | Scutching, Heckling, and other Flax Machines.   |
| United Kingdom | 6                    | Parr, Cuffis, and Madeley       | Various Machines for Carding and Spinning Cotton; Three Self-acting Mules; also various Engineers' Machine Tools. |
| United Kingdom | 128                  | Remond, A.                      | Machine for folding and gumming Envelopes.  |
| United Kingdom | 640                  | Ransomes and May (Class V.)     | Leggatt's Queen Printing Press.   |
| United Kingdom | 418                  | Robinsons and Russell           | Steam Sugar-cane Mill.  |
| France         | 1454                 | Roswag, A., and Son             | Wire-cloth for Paper-Makers.  |
| United Kingdom | 222                  | Ryder, W.                       | Forging Machine.  |
| France         | 1474                 | Sautronil, jun.                 | Machine for Planing and Moulding Wood.  |
| France         | 1475                 | Schwarber, J.                   | Forging Machine.  |
| France         | 1001                 | Schneider and Jcgrand           | Sheaving Machine.   |
| France         | 1005                 | Serivo Brothers                 | Card Clothing.  |

### CIVIL ENGINEERING, ARCHITECTURE, AND BUILDING CONTRIVANCES.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

#### Jury.

I. K. BRUNEL, F.R.S., *Chairman and Reporter*, Duke Street, Westminster; Civil Engineer.  
 CHARLES COMBES, *Deputy Chairman*, France; Member of Institute and of Central Jury.  
 Dr. NEIL ARNOTT, F.R.S., Bedford Square; Doctor of Medicine.  
 F. W. CONRAD, Holland; Engineer, Chairman of Royal Institute of Engineers at Delft.  
 J. M. RENDEL, F.R.S., 8 Great George Street, Westminster; Civil Engineer.  
 Count A. E. DE ROSEN, Sweden and Norway; Swedish Royal Navy.  
 Dr. J. V. C. SMITH, United States; Doctor of Medicine.  
 WILLIAM TITE, F.R.S., 17 St. Helen's Place, Bishopsgate; Architect.

THE works of the civil engineer and architect embrace, generally, combinations of many branches of the science of mechanics, as well as the proper application of raw materials to the various purposes of construction; and architecture, especially, includes, besides these, design in sculpture, modelling, and colour. When each of these different branches of science and of art is classed under a separate head, and the objects which illustrate any of them are removed to their separate classes, there can remain but little belonging exclusively to architecture or civil engineering. As might have been anticipated, therefore, the objects comprised in the Official Catalogue under Class VII. are not numerous, and generally speaking, are not important, although the classification of "Building Contrivances," under this head, has admitted a very great variety, including many details of construction, of every degree of importance, from the bolt of a garden-gate, and the apparatus for sweeping of chimneys, to the construction of lighthouses and the means of moving large ships.

Another circumstance has tended, also, very much to limit the extent and the importance of the contributions to this class. The works of the architect and engineer can, generally speaking, be exhibited only by drawings or models, and consequently, with few exceptions, it is the model, and not the work it represents, which has been brought before us; and the modeller, more frequently than the architect or engineer, is the exhibitor. From these causes the labours of the Jury have been comparatively light, and might have been somewhat devoid of interest but for the circumstance of two remarkable objects, one of them not included in the Catalogue, having been brought under their consideration subsequent to the commencement of their proceedings, viz., the great building in which the Exhibition is placed, and the model dwelling-houses (pp. 111, 112) which are erected near it. With respect to the first, it has been so pre-eminently successful in every respect, and by universal consent reflects such credit upon all concerned in its design and in its execution, that it is left to this Jury only to be the formal agents of recommending to the Council the awarding of the highest prize, the Council Medal, to Mr. JOSEPH PAXTON, who originated the design, and to Messrs. FOX, HENDERSON, and Co., who most ably carried it into execution.

As regards Mr. Paxton's claim, amidst the competition of the whole of Europe, he proposed that mode and form of construction of building which appeared on first sight, and which has since proved to be, the best adapted in every respect for the purpose for which it was intended. The design possessed this peculiar merit of fitness for its object, in a singular degree—there was no startling novelty being the point which could lead astray the judgment of those who had to determine upon the choice of plan, or which could in the first instance obtain, still less permanently secure, the good opinion of the public. As

regards the form of outline, which is most simple, several designs nearly resembling it had been submitted in the general competition. As to the materials, several proposals had been previously made to cover the whole area to be inclosed with glass, and iron would, of necessity, be employed for the framing. But in the combination of form and materials, in the particular mode of applying those materials, and in the adaptation of the forms to be selected to their convenient use, as well as in the various details by which the whole was rendered perfect, the design was entirely distinct in character from all that had been proposed, and appeared at once to have the one single merit of being exactly that which was required for the purposes in view. The design, as realized, has completely fulfilled every condition of utility. It has equally proved to be capable, by simple but judicious decoration, for which we are indebted to Mr. Owen Jones, of being rendered most elegant and brilliant in effect; and although very novel in its construction, it has been found, from the ingenuity and mechanical fitness with which all the details have been carried into execution, to be susceptible of rapid and moderately economical construction.

To Mr. Joseph Paxton, to whom the merit of this design is due, the Jury have recommended, and the Council have adopted the recommendation, the award of the Council Medal.

By a fortunate coincidence the execution of the design thus ably conceived was undertaken by parties peculiarly well fitted to do it justice. Considerable experience and skill were required in every detail of mechanical construction, great method in carrying out to the fullest extent a system of repetition of similar parts, and strict habits of business and of order, for organizing a system by which vast quantities of materials or of manufactured parts could be obtained with certainty from several quarters, and large bodies of workmen kept regularly employed in the rapid application of these materials and the putting together of the parts. There was also required a command of an extensive establishment, and of a staff of able assistants and superintendents. All these requisites and conditions were necessary, and in a high degree, for the purposes of rapidly determining upon all the details of construction, preparing all the working drawings, insuring the construction of the numerous parts in large quantities, and ready to be fixed with perfect accuracy in their several places; and lastly, in executing without any delay or accident, resulting from miscalculation or error of construction, or defective arrangements, a work of unusual magnitude in an unusually short space of time. All these conditions and qualifications for success, and in the requisite degree, were found combined in the persons and in the establishment of the contractors, Messrs. FOX, HENDERSON, and Co. To them accordingly the Jury also recommended a Council Medal.

Strongly contrasted with this building in its magnitude and in every one of its principal features, and in all its ostensible objects and uses, stands the Model Dwelling-house. But though contrasting in pretension, it is in importance second neither to the building itself, or to anything within the Exhibition. And in respect to the number of those whom it seeks to benefit, and the extent to which their physical and moral condition may be ameliorated, and the amount of additional comfort and happiness to be created by the simple means thus suggested of improving the dwelling of the working man, no object in the Exhibition yields to it in value, or suggests more weighty considerations for the political economist and the philanthropist.

To place within the reach of all a large proportion of those comforts most conducive to health, to habits of cleanliness and decency, which have hitherto been enjoyed as luxuries only by the few; to remove that painful necessity under which the poor man now labours of submitting to privations and inconveniences, which are destructive of moral habits and utterly inconsistent with domestic comfort, and to place at his command a certain degree almost of luxury, which tends to refine the mind, and substitutes a comfortable home for a miserable and barely efficient shelter from the elements, is the ambitious but wise and benevolent design of those who, with the example and under the leadership of His Royal Highness Prince Albert, have of late actively promoted the improvement of the dwellings of the working classes.

Separate dwellings for a few families, and many large lodging-houses have been built at the expense of private associations and individuals, as specimens of what is desirable, and examples of what may be done. These examples have already produced a marked effect upon the demands of the tenant, and upon those who have to supply the demand. But in order to secure permanently and sufficiently these benefits to the million, for whom they are intended, they must be provided at a price which the occupier can afford to pay, and which shall at the same time induce the builder to erect the houses. This has been the principal difficulty, and one which Mr. Roberts, the architect, who designed the houses now under consideration, has long laboured to overcome. The present example has been erected under the direction and at the expense of His Royal Highness, and contains all the latest improvements of general arrangement, material, and workmanship. It is fair to assume that in a new branch of industry such as this, great improvements may be made; and if so, we may hope in a very short time that the houses of the labouring classes may excel in cleanliness, equality of temperature, and perfect ventilation, the best houses now constructed for the wealthier classes.

In the houses exhibited, accommodation is afforded for a sufficient number of separate sleeping-rooms for average families. By the use of hollow bricks the walls are made to be less perfect conductors of heat and sound; and the rooms are more economically heated, and are rendered more equable in temperature. By the use of brick and stucco floors, and glazed bricks in the side walls, the whole building is rendered fire-proof, and the walls and floors cannot harbour insects, and may be kept perfectly clean at the smallest possible expenditure of time and trouble. The hollow bricks are used for air-passages in the cornices and around the upper part of the room and communicating with the chimney, in the manner practised by Dr. Arnott, and thus excellent ventilation is easily obtained. A supply of water is provided upon each floor; and the whole is stated to have been constructed at an expense which allows a set of rooms, capable of affording a really comfortable home, being let at as low a rate as is now paid for the wretched lodgings from which the poor man escapes to the street or the public-house, and to which he cannot return without disgust.

It is difficult to over-estimate the magnitude and importance of the effects of such a change upon the population of the country, whether as adding to their individual happiness, or improving their physical and moral condi-

tion, and thus rendering them more valuable and useful members of society.

The Jury have unanimously recommended to the Council that they should award the Medal reserved to their gift to His Royal Highness Prince Albert, as the exhibitor of this most useful and interesting contribution to the Exhibition, and to whom the nation at large is so deeply indebted for the promotion of this important subject.

The views of the Jury upon the merits of the two important objects for which they have recommended the Council Medal, have been stated at some length; but it will be desirable, in order to avoid any invidious distinction, to refer more generally and less in detail to those contributions for which, after the approval of the Council, it is proposed to award the Prize Medal. The order in which they will be mentioned must not be considered as indicating an attempt to classify them according to their respective merits, but as resulting from a pre-arranged classification, according to the circumstances under which the objects might be supposed to be sent. Thus models of works executed, and which were contributed by the designer and executor, and as explanatory of the design, and not as a specimen of workmanship in the model, are classed before models contributed by the modeller or by others than the authors of the works, or which are distinguished principally by perfection in the art of modelling, and both as connected more or less directly with the construction of important works in architecture and civil engineering, have been mentioned before amongst "Building Contrivances."

Amongst the limited number of models of works successfully executed, contributed by the authors of the original works, and explanatory of their designs, that which happens to fulfil most completely all the conditions of the proposed classification, is one which also well deserves mention for its merit. It is the model of the dome of the Observatory of Paris, constructed by M. P. L. TRAVERS, of Paris (p. 1044, p. 1228). The difficulties to be overcome in this work were serious. It was desired to establish on the top of an existing cylindrical wall of masonry, of about 40 feet in diameter, and having no sufficiently solid central support, a steady centre for an equatorial of large dimensions, and a revolving floor and dome of the diameter above stated, the motion of which should not affect the steadiness of the instrument. Mr. Travers has for this purpose fixed the instrument upon a small central floor, resting on a conical framework of strong iron ribs radiating from the centre and fixed into the inner surface of the cylindrical wall: a second series of radiating ribs also fixed to the wall and placed immediately to the former, carries a ring concentric to the small floor, and which serves as the centre of motion for the revolving floor and building. The building, with its dome and floor 40 feet in diameter, and weighing about 40 tons, revolves round the central guiding circle before mentioned, and upon a series of rollers working upon a ring bedded upon the wall. The attempt was a bold one: the design shows sound mechanical knowledge and skill in construction: the model illustrates the design clearly, and the result of the attempt is said to have been eminently successful.

Mr. TRAVERS (p. 1228) also exhibits a model of an excellent iron roof of 120 feet span, constructed by him for the Custon-house, Paris.

Captain Sir SAMUEL BROWN, R.N. (No. 334, pp. 331, 332), exhibits models of slips for hauling-up ships, as designed by himself, and which have for many years been successfully employed; also numerous models of works which he has executed, and of projects for various contrivances connected with the construction and moving of ships.

Messrs. S. and H. MORTON (24, p. 311), have exhibited a model of the patent slip which has so long borne their name.

Of the models exhibited under circumstances approaching nearest to the condition above named, as the models of railway drawbridges, constructed upon the Dutch railways, and sent by the Railway Company, by whose engineer they were designed and executed, and—

The model of the Britannia Bridge, contributed by Mr. E. CLARK (107, p. 321), a gentleman engaged in its construction, and whose name is closely identified with the work as the principal assistant to whom the investigation of many of the scientific questions involved in its construction, and the superintendence of the work, were intrusted. Of the first named, the works have been executed some years, and have well answered the purposes for which they were intended. The peculiar mode of opening the bridges is well worthy the study of the engineer, and the application of the principles on which they are constructed may prove highly useful. The models are perfectly well made. Of the Britannia Bridge it is unnecessary to do more than to name it. It is universally recognised as one of the finest works of the age; but the object here exhibited can be considered only as a model of the work, and is classed accordingly. In workmanship it manifests the perfection of the art of modelling, and reflects great credit upon Mr. J. James, who is stated in the Catalogue to have executed it.

Under very similar circumstances may be classed an excellently executed model of that great work, the Plymouth breakwater, contributed by Mr. W. STUART (28, pp. 311, 312), who has personally superintended the execution of the whole of these works, from the commencement in 1810.

To the exhibitors of the two models adjoining that of the Britannia Bridge, Medals have also been awarded. That of the Kief Suspension Bridge is contributed by the engineer, Mr. C. VIGNOLES (105, p. 321); but the work is not executed, and therefore, although in course of construction, can be considered only as a design. The model is by the same workman as that of the Britannia Bridge, Mr. J. JAMES, and is a most elaborate and beautiful piece of work, exhibiting every minute detail.

The model of the bridge erecting over the Wye at Chepstow, is exhibited by the contractors for the work, Messrs. FINCH and WILLEY (9, p. 310). It illustrates well the construction of the bridge, but is not highly finished.

In the American Division there is a full-sized model, or rather a portion of a bridge, illustrative of the principle of construction on which several large bridges have been erected in America. The principle is a modification of the "lattice bridge," in which iron is skillfully introduced. The design, which is by the Messrs. LUDER, exhibits that ingenuity and skill in construction for which the Americans are celebrated. It is sent by the NEW YORK IRON BRIDGE COMPANY (147, p. 1416).

Prize Medals have been awarded to Mr. SALTER (p. 851) as the exhibitor of several most beautiful models of engineering and architectural works, and to Mr. J. W. LEEMAN (257, p. 1282), who has exhibited a very beautiful model of the Cathedral of Strasbourg: and of Mr. G. MICHEL, of Berne (248, p. 1282), for an exquisite model of a Bernese farm-yard, with every detail both of interior and exterior, the Jury make Honourable Mention.

Of geographical modelling, a most perfect specimen is exhibited by Captain JENKINSON (p. 851), being the model of the Undercliff, Isle of Wight, from a trigonometrical survey, with every detail minutely and accurately given.

Mr. F. A. CARRINGTON also exhibits several excellent models of various parts of England.

Before mentioning designs for mechanical construction not yet executed, it will be right to notice Mr. W. G. WILKINS' revolving floating-light (167, pp. 326-329), in which excellence of workmanship is combined with judicious contrivances for meeting the various difficulties of obtaining a large steady burning revolving light, attached to the mast of a floating-light vessel. These lights are in use and work well.

The designs for novel construction in engineering are not numerous. Of these two have been selected as worthy of a Prize Medal, the breakwater and lighthouse of Mr. W. H. SMITH (165, p. 323), and a bridge by Mr. J. T. ROSE, of Litch (180, p. 329), in which an elegant and mechanical arrangement of timber is suggested.

Amongst building contrivances it is to be regretted that more numerous examples of heating and ventilating have not been found. But those having been generally connected with branches of manufacture, are considered in other Classes. Of the contrivances more or less connected with building, which have remained in Class VII., Major PRATT (16, p. 311) has exhibited a model of a very simple and ingenious system of steps, for landing from boats, which rise and fall with the tide, keeping at all times a complete set of steps, with a vertical rise and tread, and with a landing at the bottom, and the parts, being never covered by the water, may remain clean and dry. The model is small and unpretending, but the object is by no means unimportant, and the idea promises to be successful and inexpensive in construction. No greater merit can be ascribed to any plan, and the Jury have considered it well worthy of a Prize Medal.

To both Mr. C. E. HEISKE (53, p. 315) and Mr. A. SIENE (1, p. 309) the Jury have awarded Prize Medals for complete sets of diving-dress apparatus, alike excellent in construction and well studied in detail; each has some peculiarities, but both are good in workmanship and well designed.

In contrivances for more domestic purposes to Messrs. J. BUNNETT and Co. (152, p. 326), who have exhibited a specimen of their metal shutters, and several excellent water-closets; and to Mr. T. H. WILSON (113, p. 328) for a very ingenious contrivance for a bolt for double road-gates, which gets rid of the objectionable stop that is now used, which, rising in the middle of the road, is both dangerous for horses and very unsightly, and for a system of bolts and slides for doors, which renders them almost air-tight, and adds to their security against violence, the Jury have also awarded Prize Medals.

Amongst several objects which were allotted at a late period to Class VII., the Jury wish to draw particular attention to two sets of boring-tools from the Continent, one contributed by Mr. J. F. LAUE, of Wilders, Switzerland (65, p. 1270), constructed on a principle that has been eminently successful, in which water is introduced by means of hollow rods, and mixing with the powder or small dust formed in the boring, is discharged through the tool by the blow of the latter, in descending or by other means, and thus carries with it the produce of the boring, keeping the bottom clear and fresh to receive the full effect of the tool. A boring of 1,200 feet in depth has been made with these tools, and with a facility of which the old tools are not susceptible.

Messrs. MUMFORD and SONS, of Paris (658, p. 1209), have also exhibited a set of powerful boring-tools, similar to those with which they effected the celebrated "Puits Artesien," of Grenelle, which exceeds 1,800 feet in depth. This result is sufficient proof of the excellence of the apparatus.

Among contributors of other objects, worthy of Honourable Mention, but to which prizes have not been awarded, the Jury desire to record the names of—

Mr. T. BOUCH (73, p. 317), the exhibitor of a model of a railway ferry-boat.

Messrs. BRENNER and SONS (95, p. 318) for their models of various apparatus for working in situations exposed to the sea, and of that used to assist in getting off the "Great Britain" steam-ship.

Mr. J. DOBSON (111, p. 323), for his model of a fine roof at the Newcastle Railway Station.

Mr. G. HULWOOD (31, pp. 312, 313) for a simple apparatus for shutting and securing ships' lights.

Mr. J. LEEMANN (258, p. 1283) for a model of a fountain in the Market-place of Nuremberg, by the Sculptor Sebald Schonhofer. (Honourable Mention in Class XXX. also).

ALICE LOWE and Co. (62, p. 316) for stink-traps. Mr. T. G. NEWSHAM (170, p. 328) for models of ornamental roofs for churches and other similar buildings, of terra cotta, and also of timber, and for a construction of window-sashes, showing much ingenuity.

From Saxony some excellent models of roofs have also been sent, which deserve mention.

## CLASS VIII.

REPORT ON NAVAL ARCHITECTURE AND MILITARY ENGINEERING;  
ORDNANCE, ARMOUR, AND ACCOUTREMENTS.\*

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

## Jury.

Baron DUPIN, *Chairman and Reporter*, France; formerly Minister of Marine, Member of Institute and President of the Central Jury, &c.  
Major-General Sir JOHN BERGONIE, K.C.B., *Deputy Chairman*, 57 Pall Mall; Inspector-General of Fortifications.  
Lieut.-Col. CHATELAIN, R.A., F.R.S., Royal Arsenal, Woolwich.  
Ch. LESOINER, Belgium; Member of the Chamber of Representatives, late Merchant.  
Major MICHAUX, France.  
Sir BALDWIN WALKER, K.C.B., Surveyor-General of the Navy; Admiralty, Somerset House.  
A. WHITNEY, United States; Merchant.  
ISAAC WATTS, Somerset House; Assistant Surveyor-General of the Navy.

## Assessors.

Capt. F. W. BELCHER, R.N., Naval Department, Board of Trade.  
Lieut. CREAKE, R.E., Hon. Secretary.  
Col. HALL, R.E., Ordnance Survey Office, Southampton; Director of Ordnance Survey.  
Capt. JAMES, R.E., 34 Lambroke Square, Notting Hill.  
GLOBE LORRELL, 12 Gilly Place, Holborn; Inspector of Small Arms.  
Col. MOUX, France (Juror Class V).  
Capt. YOLKLAND, R.E., Ordnance Map Office, Southampton; Assistant Director of Ordnance Survey.

## PART I.

## NAVAL ARCHITECTURE.

It is not unworthy of remark, as being a singular feature in the maritime history of Great Britain, that whilst, during a period of war, vast improvements were being made in its military service, very little was effected for its navy until after the Treaty of Peace.

It was not until a general pacification in 1814 had freed Europe from a severe and terrible military struggle, that Sir Robert Seppings, then Surveyor of the Navy, brought forward his improved method of naval construction. The lower parts of the frames of ships of war were then for the first time filled in, and no longer afforded interstices for the accumulation of dirt and putrid water; and the frame-timbers of the bottom presented a compact mass of wood from the keel up to about the light water-line. Besides this great improvement, the whole fabric was further strengthened by means of a system of diagonal trussing, which, together with the solid bottom, opposed such resistance to the forces due to the weight of the hull and its contents acting downward, and to the forces due to the displacement or pressure of the water acting upward, as effectually to prevent the keel from shortening, and consequently the ship from hogging or breaking down in the direction of her length, as it was liable to do formerly, or otherwise yielding to the forces of pressure under sail, or those of pitching and rolling in a tempestuous sea.

In addition to these first great steps in the progress of ship-building, the upper parts of men-of-war were much improved in form and strength; the stern, instead of remaining open to the fire of an enemy, has been more strongly built, in a semicircular or rather elliptical shape, better fitted for defence in every direction. The upper decks have also been enlarged, and space gained for working the guns.

The building of ships of war has been further improved in many ways which cannot be explained here. More solidity has been obtained by greater precision in joining

the various pieces of wood constituting the ship. By such means the *working* of the timbers in a heavy sea is greatly prevented; and both solidity and greater durability are obtained.

Instead of firing the great guns by the same mechanism as old muskets, caps andammers have been adapted to them.

Advantages of still higher importance have been obtained by the introduction of guns of very large calibre, mainly due to General Paixhans, which were introduced nearly twenty years ago, and called *canons à la Paixhans*. At first very few such guns were placed in each ship; but now we find complete batteries of 68-pounders, the effect of which cannot fail to be tremendous.

The combination of large masts has been rendered more economical, easy, and solid, by the employment of coaks or cylinders of hard wood, inserted one-half of their length into each of the pieces of the masts, brought into contact.

Sir W. Symonds, who succeeded Sir Robert Seppings in 1832, as Surveyor of the Navy, turned his attention toward an improved form for ships of war, and designed them of such figure and dimensions as to require very little ballast; this he in great measure accomplished by a considerable increase of the breadth. This system had many advantages; it gave greater stability, and in sharp ships more space below for stowage, besides a larger field or deck for working the guns; and although many talented naval constructors and officers considered this form unfavourable to an easy motion at sea, and liable to distress the spars; we have, nevertheless, great cause to be thankful to this talented and meritorious officer for his laudable and unwearied endeavours to improve the construction of ships of war.

We are further indebted to Mr. J. Scott Russell, the distinguished Secretary of the Royal Commission, for a series of valuable experiments and researches on the form of least resistance at high velocity; this form being determined by examining the form of waves produced by drawing vessels through a canal at different degrees of speed. Further experiments are being made by this gentleman in the application of his deductions to

\* This Report was written in English by Baron Dupin.

sea-going ships, and he has our best wishes for their ultimate success.

The theory of stability, so important to the navy, and which we considered in a geometrical point of view, has been examined, both successfully and ingeniously by the Rev. H. Moseley, the President of Jury V.

The stowage of ships has been much improved, of late years, both in the form and disposal of stores; thus water-casks are replaced, at the suggestion of General Bentham, by iron tanks. The cubic or prismatic form of these tanks insures a great economy of space as compared with the cylindrical form of casks; they also preserve the water perfectly pure, during long voyages; casks, on the contrary, have the soluble part of their wood dissolved by the water, causing putridity, which produces various diseases, especially in hot climates.

Equally important with the improvements in keeping water free from taint, must be considered the modes invented by M. Appert for preserving all kinds of meat.

The preservation of gunpowder free from humidity, so necessary for ships of war, is now rendered perfect by the employment of hermetically sealed metallic cases, or wood cases with metallic lining: an improvement due to the British navy.

In the French navy, great improvements have been made by separating passages for the conveyance of cartridges from the magazine up to the various batteries of the ship. These arrangements were particularly remarked by the English during their visit to the French fleet at Cherbourg in 1850.

We now come to a series of improvements of the highest importance to the safety of ships. The hemp cables formerly employed were very objectionable, being liable to rapid decay, particularly in hot climates. When the anchor was cast on a rocky bottom, the cable was frequently cut by the rocks, and very often parted, so that the ship was greatly endangered.

A captain of the British navy, (Sir Samuel Brown,) introduced cables made of iron links, so arranged as to be easily worked. These chain-cables are now in general use, not only in ships of war, but also in the commercial shipping of every maritime nation. We should have been happy if so vast an improvement had been recent enough to have received the highest of our awards, as being one of the greatest effected for the shipping interests and the preservation of life and property.

The first method for stopping iron cables is due to the English: the last and best belongs to the captain of the French frigate "Legoff." A high eucopium is due to M. Barbotin, *capitaine de vaisseau* in the French service, for having devised the means by which the chain-cable can be worked on the capstan. The various links as they succeed each other fall into grooves, on the periphery of a large polygonal prism forming the body of the capstan. When the capstan is put in motion, the links of the chain-cable have in succession half their thickness lodged in these grooves, and successively disengage themselves with mathematical precision.

The improvement in cables naturally leads us to speak of anchors.

Very remarkable improvements have been recently made by Lieut. RODGER, R.N., insuring a better distribution of the metal in the direction of the greatest strains. The palm of the anchor, instead of being flat, presents two inclined planes, calculated for cutting the sand or mud instead of resisting perpendicularly; and the consequence is, that these new anchors hold much better in the ground. The Committee of Lloyd's, so competent to judge of every contrivance likely to preserve ships, have resolved to allow for the anchors of the ships they insure, a sixth less weight, if made according to the plan of Lieut. Rodger, to whom we have given a Prize Medal.

Another source of safety, most important to ships, is an efficient application of metallic conductors by which they are secured against the destructive element of lightning. Franklin made the immortal discovery of the identity of artificial electricity and that from the thunder-cloud, and through the instrumentality of the lightning-rod, devised a happy application of his discovery to the

preservation of buildings and ships in thunder storms. The variable and complicated circumstances, however, under which ships are necessarily placed, rendered the use of such rods on ship-board difficult and apparently impossible. The masts—the only parts to which they could be well applied—consist of many distinct portions; these it is often requisite to move one upon another, and sometimes to remove altogether; they are also liable to injury from wind and other forces acting on them. The defence of ships from lightning had hence been confided to a small chain or rope of wire temporarily applied along the rigging; but which, from the very nature of the case, fails to afford the full amount of security to be derived from a more powerful conductor permanently fixed along the mast. Sir W. S. Harris conceived the idea of making capacious metallic conductors an integral part of the masts and hull of the vessel, so as to bring the general fabric into that perfect conducting or non-resisting state it would assume, in respect of the matter of lightning; supposing the whole mast to be metallic throughout; this he has effected by incorporating with the masts and hull a series of copper plates, so arranged as to meet all the varying conditions of the spars, and so tied together that an electrical discharge, striking upon any part of the vessel, cannot enter upon any circuit of which the conductors do not form a part, and thus the ship is preserved from the effects of lightning at all times and under all circumstances, without the officers and crew being in any way concerned in the matter. Sir W. S. Harris has shown, by original researches in science, that in whatever position the sliding masts may be placed, a line or lines of conductors pass through the ship to the sea, affording less resistance to the passage of the electrical discharge, than any other arrangement which can be devised. The most perfect security is derived from the plan thus introduced. Sir Baldwin Walker, one of our fellow jurors, has himself experienced the great advantages of this system in a large frigate commanded by him, which was struck, both on the fore and main-masts, by heavy discharges of lightning on the coast of Mexico. In this case, the force of the discharge was such as to partially fuse the metallic point aloft on which the lightning struck, and leave spots of fusion on the surface of the conducting plates, but without the least damage being done to the spars or hull; and this, too, while the top-gallant-masts were hoisted.

We have given our highest award to this, which we consider as the best apparatus for the preservation of ships against the terrible effects of lightning.

Another source of safety in the construction of ships is the substitution of iron for wood. In a country like Great Britain, where iron is so abundant, cheap, and well adapted to various purposes, it was natural to use it instead of wood for ship-building. Iron ships have the great advantage of not being liable to that rapid decay to which wooden ships are subject, especially in hot climates; and to the dry-rot which attacks them in moist climates; iron, likewise, cannot be attacked by the worms so destructive to wood under water. Iron ships can also be made lighter, with the same bulk, as compared with wooden ships; and they resist better in case of being driven on shore or upon a bank of sand. Such are the advantages which justify the employment of iron in ship-building. In ships of war, however, the iron sheets of the hull are liable to be rent by cannon-balls in such a way as, in many cases, to render it impossible to stop the leak and save the ship. Maritime countries have, therefore, after expensive experiments, abandoned the idea of wholly substituting iron for wood, in the building of ships of war.

The rigging, blocks, and sails of ships have been improved both in their combinations and materials. The construction of blocks is managed with remarkable economy since the invention of the admirable block machinery by the late Sir J. Isambard Brunel, in his youth a French naval officer. We have awarded Prize Medals to improvements in the construction of large blocks composed of several pieces of wood, by which are obtained economy in material and a better fitting of their

hooks and rigging. Rope-making is likewise improved. We owe to British ingenuity the obtaining of equal tension amongst the threads of which the largest ropes and cables are now made, and the operation of laying the ropes, by mechanical power, with mathematical precision. The commercial marine of France exhibit cordage made in this manner, which is certainly much better than any shown on the English side of the Exhibition. Both countries have improved the texture of their sail-cloths, as will be seen by the Report of the Jury entrusted with their examination.

We shall conclude these general remarks upon Naval Architecture, with some interesting documents relative to various classes of ships, which we have before adverted to.

The Admiralty and merchant builders having contributed a large number of models of ships to the Exhibition, for the purpose of illustrating the forms and other characteristics of ships of the most recent construction: we conceived that some record of those ships should be preserved, in order to indicate the present state of naval architecture in Great Britain.

With this view we present a series of tables, containing the principal dimensions, and such other mathematical elements, relating to the construction of these ships, as could be obtained.

Table I. (page 212) contains the dimensions and calculated elements of a complete series of sailing ships, from a first-rate man-of-war to a small brig.

Within the last twenty years, ships of the navy have been constructed with greatly increased width, or breadth of beam. To some extent, this increase of breadth may have been necessary, to enable them to sustain, without too great inclination under sail, the increased weight of armament now placed on board ships of war by most naval powers. But the general opinion, founded on the result of experimental trials of these ships, with those of former years, is, that breadth of beam, when carried to excess, contributes to make the ships roll quickly, and in some cases deeply at sea.

As this is a most serious evil in ships of war, materially affecting their efficiency in the use of their guns, ships of more recent construction have had increase of length as well as of breadth given them: but the latter to a less extent; thereby obtaining the requisite amount of stability without rendering them liable to those sudden impulses produced by great breadth at the water's surface alone, which causes the side to round greatly inwards, both above and below the water-line. The ships referred to are, nevertheless, a very fine class of ships; and in the "Queen" we see a first-rate ship, combining with great speed, stability, easy motion, and every other essential property of a man-of-war.

Table II. (page 213), contains the principal dimensions and other elements of a number of frigates constructed by different persons with a view to competition. Several of these frigates have been attached to the late experimental squadron under the command of Commodore Martin, for the purpose of fully testing their sailing and other properties as ships of war. The results of these trials, in so far as they have as yet been determined, have been indicated in a Report ordered to be printed by the House of Commons, on the 1st July, 1851. The superiority of sailing was in favour of the "Phæton" over other frigates similarly fitted. Her superiority was maintained notwithstanding various changes in the trim of the rival frigates, the "Leander" and "Arethusa;" but the "Arethusa" had the advantage over the two others in respect of stowage, and she sailed better than the "Leander."

Table III. (page 214), gives the principal dimensions and other elements of several brigs which have been tried together at sea for the purpose of ascertaining their relative merits in regard to sailing and other necessary qualities for vessels of this class.

The results of the trials of the brigs, in Table III., are given in Captain Corry's Report, published in Parliamentary Paper, No. 304 (A), Session 1845.

Naval architecture, as far as it concerns ships moved by wind and sails, has thus presented to us many im-

provements. But we have now to speak of progress, by far more complete and important, in ships moved by the power of steam.

#### A. PADDLE-WHEEL STEAM SHIPS.

Many persons, in various countries, claim the honour of having first invented small boats propelled by steam. But it is to the undaunted perseverance and exertions of the American, Fulton, that is due the everlasting honour of having produced this revolution, both in naval architecture and in navigation.

When the general peace took place in 1814, there was not a single steam-ship in the ports of England; Scotland, however, had one small vessel of this kind. For several subsequent years, *steam-boats*, of small size and with very insignificant engines, were employed in rivers or along the coasts, but the idea of going far out to sea with them was considered very presumptuous.

In 1818, however, an American captain traversed the Atlantic in a steam ship, the "Savannah," touching first at England, and then proceeding up the Baltic to St. Petersburg.

About seven years after this steam was applied to railway travelling on shore; and then it was that most important attempts were made to extend the power of steam to long voyages by sea, and to the passage across the Atlantic from England to the United States. In accomplishing this, however, far more powerful engines, and much larger ships than had yet been built, were absolutely requisite. The examination and judgment of such engines will be found under the Report of another Jury (Class V.).

Steam was soon applied very generally, both to the commercial navy and to ships of war: a main object being—the application of such velocity combined with economy and safety as would induce persons to travel by sea.

To procure such a velocity, it was not enough to increase the propulsive power; it was also indispensable thoroughly to modify the forms of the vessels, to diminish the bulk of the prow and stern, to reduce the breadth and proportionally increase the length. In this way the forms of steam-ships have been made very similar to those of the galleys of ancient times; when, instead of steam power, human labour was applied to propel the vessel by means of oars, whereas, now, the mechanical force is transmitted by the paddles of wheels or screws acting longitudinally.

Such is, at present, the empire of man upon the sea, that calms, contrary winds, and adverse currents, formerly so detrimental to speedy navigation, are quite overcome. Periodical steam-ships start and arrive on fixed days, and almost fixed hours, at the ports of Liverpool or Havre and New York; as well as from London or Marseilles to Corstaintinople and Alexandria; and from Suez to Bombay, Ceylon, Calcutta, Singapore, and Hong Kong. Contracts are made between the Admiralty of Great Britain and steam Navigation Companies, obliging the vessels of the latter to cross the Atlantic and the Mediterranean, at the rate of at least 9 miles an hour, taking all the chance of contrary winds. Great Britain, ever attentive to the preservation of her maritime power, looks upon the great steam-ships, built by private Companies, and under contract with the Government, as a valuable reserve in case of war: with this view, special articles of the contracts with the Companies oblige them to build their ships of wood and not of iron, because, with the latter material, they would not be so fit for defence, as we have already explained. At the first signal of war, the Admiralty would, from this source alone, have an auxiliary steam navy of 20,000 horse power! The exertions of private speculators, and of the English Government during the last fifteen years, in securing the conveyance of letters, valuable goods, and passengers between Europe, America, Africa, and Asia, are deserving of the highest admiration. The many rich and powerful Companies engaged in promoting similar undertakings, by ordering steam ships to be built of great dimensions, either of wood or iron, so as to be at once very solid and sufficiently light, have greatly advanced

TABLE I.—PRINCIPAL DIMENSIONS AND CALCULATED ELEMENTS OF A SERIES OF SAILING SHIPS OF THE ROYAL NAVY.

| Specification of the Dimensions, and other Elements.  | Royal Albert, 120 Guns. | Queen, 116 Guns. | Allison, 99 Guns. | Hannibal, 90 Guns. | Cesar, 50 Guns. | Superb, 80 Guns. | Cressy, 90 Guns. | Cumtser, Emerald, 70 Guns. | Narcissus, 50 Guns. | Diamond, 16 Guns. | Archene, 18 Guns. | Siren, 16 Guns. | Pilot, 12 Guns. | Britannia, 10 Guns. |
|---|-------------------------|------------------|-------------------|--------------------|-----------------|------------------|------------------|----------------------------|---------------------|-------------------|-------------------|-----------------|-----------------|---------------------|
| Length of the load water-line from the fore part of stem to after part of post, in feet and inches  | 222 3                   | 204 7            | 205 0             | 207 7              | 209 10          | 191 0            | 200 9            | 181 6                      | 187 7               | 140 9             | 114 8             | 109 6           | 104 6           | 92 0                |
| Breadth on the load water-line to outside of planking, in feet and inches   | 60 10                   | 59 21            | 59 4              | 58 0               | 56 0            | 56 3             | 55 0             | 53 6                       | 50 10               | 41 4              | 35 0              | 34 0            | 33 0            | 28 8                |
| Relation of length to breadth at the load water-line  | 3.65                    | 3.45             | 3.45              | 3.57               | 3.73            | 3.395            | 3.652            | 3.392                      | 3.576               | 3.405             | 3.276             | 3.220           | 3.166           | 3.241               |
| Load draught of water, in feet and inches { forward   | 23 9                    | 24 6             | 23 5              | 23 6               | 23 6            | 23 11            | 23 3             | 22 10                      | 21 0                | 16 6              | 14 6              | 13 9            | 13 8            | 12 3                |
| Mean draught of water in relation to the extreme breadth at load-line   | 25 3                    | 26 01            | 25 3              | 24 6               | 24 6            | 25 4             | 24 3             | 24 2                       | 21 9                | 17 6              | 15 0              | 14 6            | 15 3            | 13 6                |
| Height of the lower port-sill from the load water-line, in feet and inches  | 0.402                   | 0.426            | 0.410             | 0.413              | 0.428           | 0.438            | 0.431            | 0.439                      | 0.424               | 0.411             | 0.421             | 0.415           | 0.439           | 0.449               |
| Depth of the keel and false keel below the rabbet of the keel, in feet and inches   | 7 0                     | 6 8              | 6 2               | 7 3                | 7 0             | 6 3              | 6 6              | 6 6                        | 9 0                 | 7 2               | 5 9               | 4 6             | 4 2             | 4 7                 |
| Distance of the greatest transverse section before the middle of the load water-line, in terms of its length  | 0.069                   | 0.057            | 0.061             | 0.041              | 0.026           | 0.229            | 0.066            | 0.037                      | 0.067               | 0.032             | 0.043             | 0.062           | 0.092           | 0.065               |
| Distance of the centre of displacement before the middle of the load water-line, in terms of its length   | 0.015                   | 0.003            | 0.003             | 0.000              | 0.017           | 0.008            | 0.014            | 0.006                      | 0.016               | 0.010             | 0.014             | 0.028           | 0.029           | 0.011               |
| Circumscribed rectangular parallelopipedon contained by the length of the load water-line, breadth on water-line, and mean draught of water, in cubic feet                | 331,227                 | 303,886          | 296,017           | 289,951            | 289,011         | 264,565          | 262,229          | 228,191                    | 197,361             | 98,892            | 59,193            | 52,593          | 49,936          | 33,961              |
| Displacement, in terms of the said parallelopipedon   | 0.523                   | 0.538            | 0.516             | 0.316              | 0.327           | 0.497            | 0.490            | 0.489                      | 0.469               | 0.409             | 0.382             | 0.370           | 0.390           | 0.393               |
| Area of the circumscribed rectangle contained by the breadth of the water-line, and depth from the water-line to the lower side of the rabbet of the keel, in square feet | 1399                    | 1391             | 1348              | 1305               | 1260            | 1294             | 1224             | 1164                       | 1025                | 640               | 478               | 442             | 445             | 348                 |
| Area of the greatest transverse section, in terms of the said rectangle   | 0.763                   | 0.760            | 0.713             | 0.753              | 0.729           | 0.700            | 0.692            | 0.704                      | 0.678               | 0.632             | 0.618             | 0.578           | 0.595           | 0.600               |
| Area of the circumscribed rectangle contained by the length and breadth of the water-line, in square feet   | 13519                   | 12112            | 12166             | 12039              | 11750           | 10744            | 11041            | 9710                       | 9703                | 5817              | 4013              | 3723            | 3448            | 2637                |

| Relation to the moment of sails abaft the centre of gravity of displacement to the moment of the sails before the said centre   | 0.864                   | 0.920            | 0.914             | 0.918              | 0.959           | 0.942            | 0.983            | 0.916                      | 0.968               | 1.022             | 1.24              | 1.032           | 1.144           | 1.045               |
| Area of sail in relation to the area of the greatest transverse section   | 28.9                    | 27.75            | 30.48             | 32.55              | 32.97           | 30.57            | 32.67            | 30.19                      | 34.13               | 37.68             | 40.16             | 41.73           | 36.3            | 36.25               |
| Area of sails, in square feet, in relation to the displacement  | 0.176                   | 0.178            | 0.198             | 0.216              | 0.203           | 0.211            | 0.213            | 0.221                      | 0.249               | 0.261             | 0.516             | 0.546           | 0.493           | 0.580               |

TABLE II.—PRINCIPAL DIMENSIONS AND CALCULATED ELEMENTS OF THE EXPERIMENTAL FRIGATES OF THE ROYAL NAVY.

| Specification of the Principal Dimensions and Calculated Elements.  | Arctusa.<br>30 Guns. | Indefatigable.<br>50 Guns. | Leander.<br>50 Guns. | Phaeton.<br>30 Guns. | Raleigh.<br>50 Guns. | Nankin.<br>50 Guns.    | San<br>Fiorenzo.<br>50 Guns. | Thetis.<br>38 Guns. | Inconstant.<br>36 Guns. | Durdee.<br>26 Guns. | Spartan.<br>26 Guns. |
|---|----------------------|----------------------------|----------------------|----------------------|----------------------|------------------------|------------------------------|---------------------|-------------------------|---------------------|----------------------|
| Length of the load water-line from the fore part of stem to after part of post, in feet and inches — — — — —  | 182 2                | 182 4                      | 182 8                | 185 8                | 181 6                | 187 2                  | 189 10                       | 165 8               | 161 7                   | 143 3               | 133 6                |
| Breadth of the load water-line to outside of planking, in feet and inches — — — — —   | 52 2                 | 51 6                       | 50 6                 | 49 4                 | 49 6                 | 50 8                   | 50 6                         | 46 6                | 45 4                    | 38 2                | 40 0                 |
| Relation of length to breadth at the load water-line — — — — —  | 3.49                 | 3.54                       | 3.65                 | 3.73                 | 3.66                 | 3.695                  | 3.759                        | 3.562               | 3.56                    | 3.75                | 3.337                |
| Load draught of water, in feet and inches { forward — — — — —   | 21 9                 | 20 4                       | 20 3                 | 21 0                 | 20 8                 | 21 0                   | 20 9                         | 18 10               | 18 8                    | 15 11               | 16 10                |
| Mean draught of water in relation to the extreme breadth, at load line — — — — —  | 23 2                 | 21 4                       | 21 3                 | 22 11                | 21 8                 | 22 6                   | 21 9                         | 20 4                | 19 3                    | 16 7                | 18 0                 |
| Height of the lower port-sill from the load water-line, in feet and inches — — — — —  | 0.431                | 0.404                      | 0.413                | 0.446                | 0.428                | 0.431                  | 0.420                        | 0.421               | 0.417                   | 0.425               | 0.435                |
| Depth of the keel and false keel below the rabbet of the keel, ditto  | 8 6                  | 9 4                        | 9 2                  | 3 2                  | 4 1                  | 8 10                   | 9 0                          | 8 2                 | 7 3                     | 6 0                 | 5 9                  |
| Distance of the greatest transverse section before the middle of the load water-line, in terms of the length of the load water-line — — — — —                                   | 1 8                  | 1 8                        | 1 8                  | 1 1                  | 1 6                  | 1 3                    | 1 6                          | 1 6                 | 1 4                     | 1 2                 | 1 0                  |
| Distance of the centre of displacement before the middle of the load water-line, in terms of the length of the water-line — — — — —   | 0.073                | 0.070                      | 0.071                | 0.069                | 0.086                | 0.080                  | 0.039                        | 0.042               | 0.072                   | 0.042               | 0.097                |
| Circumscribed rectangular parallelepipedon contained by the length of the load water-line, breadth on the water-line, and mean draught of water, in cubic feet — — — — —        | 0.010                | 0.012                      | 0.013                | 0.022                | 0.016                | 0.005                  | 0.013                        | 0.014               | 0.020                   | 0.027               | 0.030                |
| Displacement, in terms of the said parallelepipedon — — — — —   | 215594               | 195593                     | 192556               | 201104               | 190106               | 206230                 | 203711                       | 150828              | 138448                  | 88829               | 93023                |
| Area of the circumscribed rectangle contained by the breadth of the water-line, and depth from the water-line to the lower side of the rabbet of keel, in square feet — — — — — | 0.436                | 0.481                      | 0.427                | 0.457                | 0.473                | 0.431                  | 0.469                        | 0.447               | 0.440                   | 0.403               | 0.398                |
| Area of the greatest transverse section, in terms of the said rectangle — — — — —   | 1085                 | 1008                       | 970                  | 1001                 | 973                  | 1038                   | 997                          | 841                 | 797                     | 576                 | 657                  |
| Area of the circumscribed rectangle contained by the length and breadth on water-line, in square feet — — — — —   | 0.649                | 0.716                      | 0.651                | 0.720                | 0.679                | 0.662                  | 0.698                        | 0.639               | 0.660                   | 0.625               | 0.621                |
| Area of the greatest transverse section, in terms of the said rectangle — — — — —   | 9511                 | 9390                       | 9224                 | 9158                 | 8984                 | 9482                   | 9386                         | 7703                | 7325                    | 5466                | 5340                 |
| Depth of the centre of gravity of the greatest transverse section, in terms of the mean draught of water — — — — —  | 0.819                | 0.809                      | 0.821                | 0.797                | 0.851                | 0.814                  | 0.842                        | 0.846               | 0.820                   | 0.803               | 0.810                |
| Distance of the centre of gravity of the load water section from the middle of the load water-line, in terms of the length — — — — —  | 0.343                | 0.356                      | 0.332                | 0.369                | 0.349                | 0.345                  | 0.386                        | 0.318               | 0.370                   | 0.327               | 0.344                |
| Height of centre of effort of sails above the load water-line, in feet — — — — —  | Abaft                | Abaft                      | Abaft                | Abaft                | Before               | Abaft                  | Before                       | Before              | Before                  | Before              | Before               |
| Distance of centre of effort of sails before or abaft the centre of gravity of displacement in relation to the length of the load water-line — — — — —                          | 0.046                | 0.097                      | 0.062                | 0.069                | 0.0204               | 0.001                  | 0.005                        | 0.002               | 0.006                   | 0.005               | 0.001                |
| Relation of the moment of the sails abaft the centre of gravity of displacement to the moment of sails before the said centre — — — — —   | 75.93                | 77.63                      | 76.20                | 76.20                | 78.70                | 76.94                  | 77.33                        | 70.70               | 70.50                   | 61.70               | 61.50                |
| Area of sails in relation to the area of the greatest transverse section — — — — —  | Before               | Before                     | Before               | Abaft                | Before               | Before                 | Before                       | Before              | Before                  | Abaft               | Abaft                |
| Area of sails, in square feet, in relation to the displacement — — — — —  | 0.008                | 0.002                      | 0.016                | 0.006                | 0.011                | 0.009                  | 0.004                        | 0.007               | 0.015                   | 0.011               | 0.024                |
| By whom designed — — — — —  | 0.943                | 0.977                      | 0.897                | 1.025                | 0.922                | 0.933                  | 0.976                        | 0.964               | 0.904                   | 1.064               | 1.180                |

the science of naval architecture. We have to award Medals to several eminent shipbuilders who have presented the Exhibition with models of the excellent steamships which they have lately designed and constructed.

We should have been glad if the great maritime nation of America, instead of sending incomplete and imperfect models or drawings of their steamships, had furnished us with the requisite data for estimating the degree of perfection arrived at by their best shipbuilders, so as to have enabled us to recognize their incontestable merit. The United States cannot, at present, compete with Great Britain in the number of their great and regular communications by steamers, although on the lines opened by them, they are nothing inferior to their mighty rivals. The depth and vastness of the rivers of the United States, such as the Mississippi—the greatness of their lakes, which are indeed so many inland seas, have enabled the Americans to build steamers which may be considered as floating cities, and which satisfy the wants of the greatest way-faring nation of the world. The Americans, however, are to be reproached for their recklessness, and the little care they take to avoid evident peril. Catching fire, blowing up, or foundering from the effects of the latter—accidents which a little foresight might have prevented—are considered and accepted by them as casualties very little to be regarded. They brave these dangers knowingly, and to meet competition with a rival ship. Hence the accidents which occur are frequent and dreadful, and still they do not teach the commercial navigators to be more circumspect. The steamships of war, however, reserving danger for the time of battle, exhibit, on the contrary, a prudence which makes velocity subservient to security.

In the British navy much has been done, experimentally, for the best application of steam power to naval architecture. We shall notice, in our reports, the results of these experiments, which are well worthy of attention. The experiments we allude to are mainly relative to navigation with recently adapted screw propellers. This method of propulsion has the advantage of acting entirely under water, and is consequently protected from the fire of an enemy, an advantage not possessed by paddle-wheels. Paddle-wheels, also, by the large space they occupy on both sides of the ship, do not permit the use of guns along the whole length of the deck.

Several French professors, engineers, and naval officers, have made some interesting experiments on steam propulsion, with ships varying in form and size. The researches and experiments of Messrs. Bourgois and Moll have been already proclaimed and recompensed by the National Institute of France. These gentlemen are still pursuing their inquiries at the great manufactory of steam-engines for the French Marine at Indret.

We much regret that the maritime nations of the Continent did not contribute examples of their naval architecture to the great Exhibition. The Norwegians and Swedes, those excellent and bold navigators, have not sent any models or designs of the ships they employ either on the ocean or the Baltic. Their shipbuilders, inheritors of the science and art of the celebrated Chapman,\* would have figured honourably, even in comparison with the most advanced seafaring people.

Since the last change in the navigation laws of Great Britain, the Anglo-Maltese purchase merchant-ships of the Greeks, and have them registered with those of the United Kingdom—finding these ships of very little cost, and well adapted to the navigation of the much intersected seas of the Cyclades and other parts of the Levant. The Greeks, however, did not send us models of any of their ships. The Venetians, the Genoese, and even the Dutch, a maritime people both by nature and necessity, failed also to send models. Finally, we regret that the French shipbuilders of Havre, of Nantes, of Bordeaux, and of Marseilles, who do not want either ingenuity, learning, or experience, have not contributed in any way to this Exhibition. We had only from that country a model of the great iron steamers which are built for the

navigation of the Rhone, the most rapid and dangerous of the French rivers. M. Schneider,\* of Creuzot, constructed these ships and their machinery.

In twelve years there have been built at Creuzot, for the Rhone, under the direction of M. Schneider, 18 steamers, the first of 89 horse-power, and the last of 300, to carry 620 tons, and to overcome a mean velocity of the Rhone equal to at least two metres per second, ascending from Arles to Lyons in 36 or 38 hours. Other steamers, built for passengers, make still quicker voyages. Machinery for war steamers has been constructed for the French Government, at Creuzot, of 453 and of 609 horse-power, with remarkable success.

#### SCREW-PROPELLER STEAM SHIPS.

The application of the screw-propeller to ships of war is of comparatively recent date, but has, notwithstanding, been so successful as to lead to the expectation that it will ultimately be generally applied to ships in the navy, either with full or auxiliary steam-power. The first ship in the navy to which the screw-propeller was applied was the "Rattler," of 888 tons, in which, with engines of 200 horse-power, a speed of 10 knots per hour was obtained.

The results of the trial of the "Rattler" with the "Alecto," a ship built from the same lines, and having engines of the same nominal horse-power, but fitted with paddle-wheels, proved so highly favourable to the screw-ship, that the Admiralty, in the year 1845, were induced to order four old ships of the line of 74 guns, and four old 46-gun frigates, to be fitted with screws, with a view to their being employed as block-ships, or harbour guard-ships. The "Blenheim," "La Hogue," and "Ajax," three of these ships, were therefore fitted with screws and with engines of 450-horse power, and have been recently tried at sea. The speed obtained so greatly exceeded anything contemplated, whilst their efficiency as men-of-war, for general service, became so fully established, that they are no longer regarded as fit only for harbour service, but are considered as sea-going ships, possessing powers and capabilities far exceeding those of ordinary sailing ships.†

The speed obtained by steam-power alone, varies, in these ships, from  $6\frac{1}{2}$  to  $7\frac{1}{2}$  knots per hour; and by sail and steam combined, a speed of about two knots more than that which sail alone would give, is frequently obtained, with the power of sailing closer to the wind.

The forms of "La Hogue," "Blenheim," and "Ajax," although more or less altered abaft, to adapt them for the screw-propeller, cannot be regarded as altogether well suited for its effectual operation. Daily experience shows that much greater comparative length than these ships possess, combined with a bow or entrance, as well as a fine run, is necessary to ensure the best results from the screw.

By comparing the dimensions of ships in the mercantile navy with those of the royal navy, it will be seen that screw-ships, for this service, are of still greater comparative length than in the royal navy; and that, in consequence, still better results have been obtained.

The following table (see p. 216.) contains the dimensions and some of the calculated elements of a series of screw-ships of the most recent construction.

#### ENUMERATION OF THE AWARDS FOR NAVAL PURPOSES.

##### Council Medals.

1. To the ADMIRALTY OF GREAT BRITAIN (p. 344), for a magnificent set of models of ships moved either by sails

\* To M. Schneider, when minister, we are indebted for the selection of the thirty-six French Jurors and Associates sent to the Exhibition.

† As soon as the conditions of this new problem of naval architecture were known to the public, Baron, Charles Dupin, in a report to the French House of Peers, announced in positive and strong terms, the great success to be expected from men-of-war so fitted. He pointed out the new services which they could fulfil, not merely as harbour guard-ships but as a squadron of attack, for the remotest points of the European seas, and even farther.

\* The eminent author of *Architectura Navalis Mercatoria*, Stockholm.

TABLE IV.—PRINCIPAL DIMENSIONS AND CALCULATED ELEMENTS OF SHIPS-OF-WAR fitted with SCREW-PROPELLERS.

| Specification of the Dimensions, Elements, &c.  | St. Jean d'Acre, 100 Guns. | Agamemnon, 50 Guns. | Imperieuse, 50 Guns. | Arrogant, 46 Guns. | Tribune, 30 Guns. | Highlander, 20 Guns. | Archer, 12 Guns. | Cypriote, 16 Guns. | Reynold, 10 Guns. |
|---|----------------------------|---------------------|----------------------|--------------------|-------------------|----------------------|------------------|--------------------|-------------------|
| Length on the load water-line from the fore part of stem to after part of post, in feet and inches  | 240 6                      | 231 6               | 214 8                | 202 4              | 192 10            | 191 3                | 180 6            | 160 4              | 147 6             |
| Breadth on the load water-line to outside of planking, in feet and inches   | 55 4                       | 55 4                | 50 0                 | 45 6               | 43 0              | 36 0                 | 33 10            | 31 10              | 27 7              |
| Relation of length to breadth at the load water-line  | 4-346                      | 4-184               | 4-293                | 4-446              | 4-484             | 5-312                | 5-335            | 5-037              | 5-348             |
| Draught of water, in feet and inches, to load line { forward  | 23 6                       | 23 6                | 21 0                 | 19 0               | 17 3              | 15 6                 | 13 11            | 12 0               | 11 3              |
| Mean draught of water in relation to the extreme breadth at the load-line   | 25 0                       | 24 0                | 21 9                 | 20 0               | 18 9              | 16 0                 | 14 5             | 14 0               | 12 6              |
| Height of the lower port-sill from the load water-line, in feet and inches  | 0-438                      | 0-421               | 0-427                | 0-428              | 0-418             | 0-437                | 0-419            | 0-408              | 0-430             |
| Depth of the keel and false-keel below the rabbit of the keel, ditto  | 6 6                        | 6 5                 | 9 6                  | 9 6                | 7 6               | 11 2                 | 9 4              | 8 9                | 6 11              |
| Distance of the greatest transverse section before the middle of the load water-line, in terms of the length of the load water-line                             | 1 0                        | 1 0                 | 1 0                  | 1 4                | 1 0               | 0 9                  | 1 0              | 1 0                | 0 11              |
| Distance of the centre of displacement before the middle of the load-line, in terms of the length of the load water-line  | 0-032                      | 0-049               | 0-055                | 0-061              | 0-059             | 0-031                | 0-029            | 0-035              | 0-033             |
| Circumscribed rectangular parallelepipedon contained by the length of load water-line, breadth on the water-line, and mean draught of water, in cubic feet      | 0-034                      | 0-023               | 0-025                | 0-013              | 0-033             | 0-034                | 0-012            | 0-024              | 0-015             |
| Displacement in terms of the said parallelepipedon  | 322692                     | 204211              | 229696               | 179317             | 149250            | 108439               | 86526            | 66343              | 48323             |
| Area of the circumscribed rectangle contained by the breadth of the load-line, and depth from the load-line to the lower side of rabbit of keel, in square feet | 0-395                      | 0-398               | 0-497                | 0-504              | 0-498             | 0-560                | 0-506            | 0-502              | 0-500             |
| Area of the greatest transverse section, in terms of the said rectangle   | 1386                       | 1259                | 1020                 | 827                | 731               | 540                  | 446              | 382                | 304               |
| Area of the circumscribed rectangle contained by the length and breadth on load-line, in square feet  | 0-837                      | 0-838               | 0-725                | 0-733              | 0-756             | 0-862                | 0-838            | 0-828              | 0-834             |
| Depth of the centre of gravity of the said rectangle  | 13807                      | 12809               | 10733                | 9206               | 8292              | 6885                 | 6106             | 5103               | 4071              |
| Depth of the centre of gravity of the greatest transverse section, in terms of the mean draught of water  | 0-838                      | 0-865               | 0-831                | 0-823              | 0-821             | 0-825                | 0-777            | 0-798              | 0-792             |
| Distance of the centre of gravity of the loadwater section, from the middle of the load water-line, in terms of its length                                      | 0-426                      | 0-413               | 0-364                | 0-363              | 0-377             | 0-412                | 0-335            | 0-315              | 0-415             |
| Height of centre of effort of sails above the load water-line, in feet  | Before                     | Before              | Before               | Before             | Before            | Before               | Before           | Before             | Before            |
| Distance of the centre of effort of the sails before or abaft the centre of gravity of displacement, in relation to the length of the load water-line           | 0-1073                     | 0-1001              | 0-109                | 0-068              | 0-011             | 0-013                | 0-011            | 0-008              | 0-0095            |
| Relation of the moment of the sails abaft the centre of gravity of displacement to the moment of sails before the said centre of gravity                        | 83-75                      | 84-75               | 76-8                 | 73-6               | 70-1              | 58-6                 | 53-4             | 52-6               | 43-8              |
| Area of sails in relation to the area of the greatest transverse section  | Before                     | Before              | Before               | Before             | Abaft             | Abaft                | Before           | Abaft              | Before            |
| Area of sails, in square feet, in relation to the displacement in cubic feet  | 0-037                      | 0-008               | 0-018                | 0-0197             | 0-005             | 0-014                | 0-011            | 0-0056             | 0-0075            |
|   | 0-912                      | 0-923               | 0-987                | 0-877              | 1-038             | 1-109                | 0-905            | 1-047              | 0-947             |
|   | 27-1                       | 27-5                | 33-2                 | 36-9               | 36-5              | 31-6                 | 31-8             | 34-4               | 32-8              |
|   | 0-154                      | 0-103               | 0-212                | 0-248              | 0-271             | 0-292                | 0-271            | 0-327              | 0-343             |

or by steam, of the most recent construction, some of them not yet finished; consisting of—

1. A series of sailing ships of all classes, from the "Queen"—a first-rate man-of-war—to a brig of 10 guns (146, p. 344, and illustration).
2. A series of screw-ships of various classes, from the "St. Jean d'Acre," of 100 guns, to a sloop of 12 guns.
3. A series of experimental frigates.
4. A series of experimental brigs.
5. Models of bows and sterns.
6. Transverse sections.

The Admiralty, by the comparative trials they have ordered, have contributed in a very high degree to the most recent progress of naval architecture. They have equally contributed to the progress of hydrography, as I shall explain when speaking of the maps presented to the Exhibition, which are included in this award of the Council Medal.

2. To Sir WILLIAM SNOW HARRIS (150, pp. 345, 346, and illustration). Science and humanity proclaim the merits of Sir W. Snow Harris's inventions. He has exhibited practical models of his system of attaching lightning conductors to the masts or hulls of ships, which has been for several years in general use in the British Navy.

As a means of preserving life and property from the effects of lightning, nothing has proved more completely successful and effectual than these conductors. The transmission of the electrical discharge from mast to mast, and finally from the conductors in the hull to the water, is perfectly effected under all circumstances, and in every position of the spars or of the ship when pressed by sail, and without demanding any care or attention on the part of the officers or crew. The mechanical arrangement of the plates forming the conductor, which is of great capacity, is such as to admit of their accommodating themselves to any flexure the spars can sustain, whilst at the same time they preserve a fair and continuous conducting line. The various branches or subdivisions in the hull allow of a free dispersion of the electrical agency in all directions to the bottom of the ship, and into the sea, by which the tension in any one point is so reduced that explosive action is next to impossible. For these reasons a Council Medal is awarded to Sir W. Snow Harris.

3. To His Grace the DUKE OF NORTHUMBERLAND (136, pp. 342, 343). To the humanity of His Grace the Duke of Northumberland, to his unbounded liberality and generous encouragement of practical science, we owe the numerous efforts of able men to construct life-boats calculated to meet the perils of an ocean tempest. They must be easy to manage, in order to accomplish the great object for which they are designed, viz., the saving of life and property endangered by shipwreck. His Grace, with this philanthropic view, has expended some thousands of pounds in obtaining for the coasts of Northumberland, an improved class of life-boat, designed and built in consequence of the premiums the noble Duke has offered. Models of these very boats figure amongst the most valuable contributions to the Great Exhibition, and furnish a splendid example of liberality in the cause of humanity and practical science never surpassed, if ever equalled. Such are the motives under which we have judged His Grace the Duke of Northumberland worthy of receiving the Council Medal.

#### PRIZE MEDALS.

##### A. SHIP-BUILDING.—*British Department.*

The Honourable the CORPORATION of LONDON, for illustrations of the art of ship-building for the commercial marine, almost all showing the greatest and most important improvements in strength, symmetry, and efficiency; and mostly coming from establishments within the jurisdiction of the port of London.

Mr. T. I. DITCHBURN (30, p. 434), for models of paddle and screw steam-vessels, both wood and iron, designed and built by him for various services, including yachts.

Messrs. GREEN (131, p. 342), at Blackwall, for a model of the fine merchant vessels designed and built by them for the East India trade.

Messrs. C. J. MARE and Co. (149, p. 344) for models of fine sailing and steam vessels, both paddle and screw, designed and built by them for various merchant services, including yachts.

Messrs. ROBINSONS and RUSSELL (193, p. 349), for fine models of steam-boats, designed and built by them.

The ROYAL THAMES YACHT CLUB (294, p. 359), for models of the vessels belonging to their Club, which are of a most interesting character.

Messrs. THOMAS and WILLIAM SMITH (395, p. 360), for a model of the fine merchant vessel designed and built by them for the East India trade.

Mr. JOSEPH WHITE (36, p. 336), for fine models of vessels, designed and built by him for the merchant service, including yachts.

Messrs. T. J. and R. WHITE (36A, p. 336), for models of fine sailing and steam-vessels, designed and built by them for the merchant service, including yachts.

Messrs. MONEY WIGRAM and SONS (56, p. 336), for models of fine classes of sailing and steam-vessels, both paddle and screw, built by them for various merchant services.

##### *French Department.*

M. BARBOTIN, captain of the French Navy (1083, p. 1230), for his improved capstan for ships of war, adapted to the use of chain cables.

M. LAURE, of Havre, Seine Inférieure (285, p. 1190), for an insubmersible boat for the use of the military and commercial services, combining very ingenious arrangements.

M. LE GOFF, captain of a frigate in the French Navy (1083, p. 1230), for his powerful stopper in the management of chain cables.

M. SCHNEIDER, of Creuzot (1475A, p. 1246), for a large specimen of the machinery of the steam-boat "L'Océan," built by him, for the River Rhone, by which great speed and convenience have been obtained.

M. SOCIET, engineer of the French Navy (1478), for his valuable apparatus for distilling salt-water on board ships of war.

M. ROCHER, of Nantes (991, p. 1226), for his large apparatus for distilling salt-water on board ships of war, and for his inexhaustible submarine condenser.

##### *American Department.*

Mr. S. M. POOK (446, p. 1464), and Mr. W. DARTON (449, p. 1464), exhibiting through the National Institute of Washington, for several models of ships of war and large merchant vessels.

##### B. VARIOUS OBJECTS CONNECTED WITH THE NAVAL SERVICE.

Mr. C. ANSELL (185, p. 348), for a gunning punt, on a new principle, for fowling purposes.

The Rev. E. L. BERTHOE (104, p. 339), for models—1st. Of his patent perpetual log, for indicating the speed and leeway of ships. 2nd. Of his patent clinometer, for showing the inclination and trim of ships. 3rd. Of a collapsible life-boat, combining in its construction, strength, capacity, and lightness; and which under many circumstances might be found most serviceable, more especially in travelling over-land in a country where rivers have to be crossed.

Sir SAMUEL BROWN, Capt. R.N. (334, pp. 331, 332), the inventor of the chain cables introduced in sea service, for suspension bridges and piers, and for a model of ingeniously disposed slips for the purpose of hauling up ships to repair.

Mr. ALFRED FOX, for fine specimens of nets, seines, &c., for pilchards.

Mr. J. J. GROOM, for fine specimens of deep sea fishing-lines and hooks.

Messrs. JEFFERY, WALSH, and Co. (188, pp. 348, 349), for the marine glue, most successfully used as a substitute for pitch in the beams of decks, as well as for uniting large timbers for naval purposes.

Lieut. JAMES RIGMOLDEN, R.N. (291, p. 359), for the model of his plan of lanyard plates for setting-up the standing rigging of ships.

Lieut. W. RODGER, R.N. (336, p. 361), for his very remarkable improvements in the form and proportions of anchors.

Mr. J. E. SAUNDERS (Class XXIX.) for the model of a smack for fishing, fitted with an auxiliary screw propeller, being a new application to vessels of this description.

Messrs. J. and T. W. SIMMONS (124, p. 340) for the model of a "Mount's Key" fishing-boat, which is a very fine description of boat for its purpose.

Mr. S. SMITH (125, p. 340), for a model of a spring machine for knocking ships of any dimensions, offering an ingenious and ready means for setting up a design in model.

Mr. G. TUTT (Class XXIX., 185), of Rye, for the model of a "Hastings" fishing-lugger, which is also a very good description of boat for its purpose.

The following competitors for the prize of one hundred guineas, offered by His Grace the Duke of Northumberland, to mark our sense of the excellence of the models they furnish:—

Mr. JAMES BEECHING (136, p. 342), Mr. HENRY HINKS (136, p. 343), Mr. WILLIAM THASDEL (136, p. 343), Mr. J. PLENTY (p. 343), Mr. E. PELLEW (p. 342).

*Pecuniary Rewards.*—Mr. JOSEPH BOWWAY, for improvements in the construction of blocks combining strength with much less weight, and other advantages, 50*l*.

Mr. DAVID HARVEY (159, p. 346) for the excellent execution of the small model of the "Victoria and Albert," royal yacht, 40*l*.

Mr. ALEXANDER BIRNIE, of Peterhead, for nets, lines, and hooks, 50*l*.

Mr. H. DEMPSTER (174, p. 348) for an ingenious system of signals for merchant ships, 20*l*.

Messrs. THOMAS BILDS and Co., of Rotherhithe, exhibit a model illustrative of a novel arrangement of the frame timbers, with a view to increase the strength of the fabric of merchant ships, and add materially to their durability.

Mr. JOSEPH WELD (186, p. 348), of Lulworth Castle, shows a model of a 12-gun brig of war, with a view to obtain, scientifically, the advantages of speed.

Messrs. J. and J. LONG and Co. (71, p. 337), present several plans of steering wheels of very simple construction, giving to the helmsman a perfect control over the rudder.

#### C. NAUTICAL INSTRUMENTS.

This Jury had but a part of the collection of "Philosophical instruments in use for the navy," left to its examination, the other portion being retained by Jury X.

We would particularly refer to an azimuth compass, coming from the Compass Department of the Admiralty (p. 344). This instrument, for making observations at sea, combines improvements in workmanship, suggested by long experience; the centering and adjustments are very good. This excellent piece of art merits a Prize Medal, but being a Government instrument no award has been made to it.

We award a Prize Medal to Mr. F. J. DENT (Class X. 55, pp. 413, 414), for his marine compass. It has long been a desideratum to construct a compass that should not be disturbed by the motion of the ship, or by the firing of the guns. One of Mr. Dent's compasses has been, by order of the Admiralty, repeatedly tried at sea, and particularly on board the "Excellent," as to the effect of cannon upon it. Even during heavy weather, with the sea any where *before the beam*, the reports are highly favourable. The firing of heavy cannon within nine feet of the compass had no visible effect upon it; whilst the ordinary compasses deviated several points. In boats, the same instrument has also been found particularly steady.

The particulars of this instrument are—first, excellent workmanship; its card is fixed upon a vertical spindle, instead of upon a pivot resting in a cup, and it is retained in its horizontal position by the bowl having a pendulum action. The disturbing effect which both gravity and dip would have upon a magnet fixed on a spindle when out of the perpendicular, has been considered by Mr.

Dent, and a compensating power applied. A second instrument of similar construction, but with a double needle upon gimballs in the centre of the spindle has been also presented by Mr. Dent, but it has not yet been tried at sea. Here the motion given to the needle, if duly balanced, seems to be an improvement.

A third instrument of Mr. Dent's, a portable azimuth compass, is worthy of notice as an ingenious invention to overcome errors in the centering of the needle, and in the direction of the magnetic axis as placed by the maker, by a method of inverting the box, not hitherto in use.

The Prize Medal is also given to Messrs. NAPIER and Son of Lambeth (Class VI., 158, p. 285), for an instrument for registering the magnetic course of a vessel as actually steered. The card, as usual, is placed upon a cup centred in a brass pillar; but this pillar, instead of being attached to the bottom of the bowl, protrudes, and is attached to machinery which partakes of the motion of the bowl. Every three minutes the pillar carrying the card is raised by the machinery, and the card receives a puncture from a fine point placed above it, in the direction of the ship's head, and attached to the bowl inside the glass cover, after which it descends immediately to its former position. In the course of twenty-four hours the point is drawn from the circumference of the card towards its centre, passing over twenty-four concentric circles which mark the hours; so that not only is any alteration of the course detected, but the hour at which it occurred is also shown by the card. This compass, with the aid of the log, may be said to form a traverse table of the ship's route for the day.

Honourable Mention is given to Mr. HUGHES (Class X., 691, p. 472\*), for his compass in spirits. Such an instrument has been found valuable in heavy seas during the firing of cannon, and especially in boats; but hitherto the necessity of leaving a space in the bowl (which has, until now, been of metal), has produced an injurious effect upon the needle and upon the steadiness of the fluid. Mr. Hughes has overcome this evil of the air-bubble by an elastic bottom. His instrument is further recommended by its cheapness.

#### American Department.

Mr. ST. JOHN\* of Buffalo (95, p. 1439), deserves the Prize Medal for his compass, which, to the ordinary one, adds two small needles placed upon pivots over the east and west points, with indices pointing towards the centre of the card, and each having a graduated circle marked *E* and *W*, on either side of their zero points. These small needles are called *satellites*; their object is to show the presence of any disturbing force upon the needle, and also to indicate, by the mean of their readings, the amount of the deflection; but this last desideratum is not yet obtained. The invention is, however, new and ingenious, and if it could be improved in this respect, it would become an instrument of great practical importance on board vessels, especially in those of iron.

#### D. INSTRUMENTS FOR MEASURING THE RATE OF A VESSEL THROUGH THE WATER.

One instrument of this kind is mentioned for an award in the section of Naval Architecture, and belongs to the Rev. F. L. BATHON.

Two other instruments for measuring the rate of a vessel through the water are due to Mr. ST. JOHN (542, p. 1468), who received a Prize Medal for his compass. One of his instruments consists of a rotator, which acts upon a spindle protruding through the bottom of a vessel by means of a copper cylinder in the hold rising above the water-line of the ship. The other consists of a small instrument connected with and disengaged from the ordinary log-line, by the turning of the glass which measures the interval.

Messrs. ELLIOT and Sons, of the Strand, London (320, p. 443), exhibit two small convenient instruments for measuring the rate of running water. They are very

\* This exhibitor has been awarded a Prize Medal by the Jury of Class X., in whose list his name appears.

portable, and have been used by civil engineers with success.

#### E. INSTRUMENTS FOR MEASURING THE DEPTH OF THE SEA.

A Prize Medal is given to Mr. ERICSSON,\* of New York (Cl. X., 146, pp. 1442-1446) for his instrument for measuring depths by the compression of atmospheric air. It is a modification of the one known in the British Navy as *Ericsson's Sounding Lead*. Capt. Beechey, R.N., one of our fellow-jurors, made use of it for several years in a ship under his command; and experience has shown him that it was a good instrument when the depths were under 50 fathoms. Mr. Ericsson attributes the idea of his instrument to Mr. Agden. But seventeen years before it came out, Sir Humphry Davy's *water-bottle* was in use in the polar expeditions; an instrument upon the same principle, although greatly inferior to Mr. Ericsson's in the extent of its scale.

|   |       |       | Fathoms. |
|---|-------|-------|----------|
| In 51 casts, extreme difference of Ericsson's lead from the truth | -     | -     | +24      |
| In 47 ditto   | ditto | ditto | +23      |
| In 49 ditto   | ditto | ditto | +22      |
| In 47 ditto   | ditto | ditto | +2       |
| In 48 ditto   | ditto | ditto | +23      |
| In 51 ditto   | ditto | ditto | +12      |
| In 51 ditto   | ditto | ditto | +1       |

All the depths here mentioned were under 50 fathoms.

#### F. APPARATUS FOR SAVING LIFE.

Having already awarded medals to the inventors of boats for saving men's lives and property, we have here to consider other means for effecting the same object.

##### 1. By effecting a communication to and from a Ship in peril and the Shore.

We must, in the first instance, mention here Capt. W. G. MANBY, R.N. (22, p. 335), so long known as the introducer and zealous promoter of the object of saving life from shipwreck, by means of firing a projectile, with a line attached to it, from the shore to the ship, which has been used with great success along the coasts of Great Britain, and has rendered remarkable service.

M. G. DELAIGNE, of France (473, p. 1200), employs a howitzer to obtain the same result as Captain Manby. This invention involves this new principle, that a portion of the line to be carried is contained in the projectile. The idea seems capable of successful application.

Captain JERNINGHAM (21, p. 335), of the British Navy, has an anchor of a particular form, which he proposes to fire from a Manby's mortar, in sufficient numbers to afford the means of hauling a life-boat through the surf.

Prize Medals have been awarded to the above three Exhibitors.

Mr. GRENKE (59, pp. 336, 337) exhibits a method of discharging a rocket, with a line attached, from a harpoon gun. When discharged the rocket ignites, and is said to prolong the range to a greater distance than would be effected by either the gun or the rocket alone. The gun is distinguished for its lightness and efficient construction.

Mr. A. G. CARTE (29, p. 335). This exhibitor has been distinguished by his great zeal in carrying out the object of saving life by means of a rocket. His plan is, to employ a war rocket, instead of the well-known rocket of Dennett.

##### 2. By means of Rafts, &c.

Mr. W. G. RHIND, of Ross, Herefordshire (290, p. 354), presents various models of deck-seats and benches for

steamers, so constructed as to be readily formed into rafts, each one sustaining eight persons. A Prize Medal is awarded to Mr. Rhind.

##### 3. By means of Buoyant Air-tubes.

Mr. S. W. SILVER (195, p. 350), exhibits buoyant mattresses, manufactured according to Mr. Laurie's invention. Mr. Silver connects numerous waterproof tubes, partly distended with horse-hair, woollen flocks, or cocoanut fibre, in such a manner, that in case of accident happening to one or more of these tubes, the others may be sufficient to sustain the required weight on the water. The tubes are made up into mattresses, pillows, and also into floats, to be placed under the thwarts of boats.

A mattress, weighing only 17 lbs., sustains in the water 284 lbs. A pillow sustains 28 lbs. Mattresses for emigrant vessels, sold at 9s., sustained 96 lbs. in the water for five days, without being in the least affected. A Prize Medal is awarded to Mr. LAURIE as the inventor (195).

Mr. A. G. CARTE (29, p. 335), already mentioned, exhibits a very simple, cheap, and efficient life-buoy, which has been in general use since 1838, and is reported to have preserved 400 persons from drowning. A Prize Medal is awarded to Mr. Carte.

Messrs. ESDALES and MARGRAVE (126, p. 340) exhibit floating mattresses, filled with cork shavings; worthy of praise.

## PART II.

### MILITARY ENGINEERING, ORDNANCE, ARMOUR, AND ACCOUTREMENTS.

When I first visited Great Britain, very soon after the general peace in Europe, I found a very strong prejudice against the value of military institutions, and everything belonging to the army of this country. It may be easily conceived that foreigners would be anxious to learn everything connected with the navy; but nobody imagined that the land forces could present models deserving the closest attention of military observers. Having visited, however, the great arsenal of the Ordnance at Woolwich, the schools for the engineers and their troops at Chatham, and the school of the general staff at Farnham, I was deeply convinced that, on the contrary, Great Britain merited the most attentive observation in order to appreciate duly the high value of her land military forces, institutions, and exercises. At this period she possessed the best system of land-artillery, a system which united solidity, simplicity, security, and rapidity. The carriages for field-pieces allowed the gunners to be carried along with the guns, as rapidly as light cavalry, as well as the caissons which contained the necessary ammunition. All the wheels, before or behind, of every kind of carriage for the field batteries, being equal and identical, could be replaced most easily; the draft being more easy, and the overthrow of the carriage more difficult.

Such were some of the rare qualities, due to the exertions of General Congreve, of an artillery which all the military powers adopted very soon after a description of it had been published.\* To General Congreve also is due the employment of rockets in the army, as projectiles.† They wanted at first the most important quality of precision in the direction. A better construction by degrees overcame this difficulty. The French, the Germans, the Prussians, &c., have studied this new kind of weapon, and tried the use of them in warfare; but not with very great effect.

Fortifications did not present novelties of so high a value, but still they deserved to be studied in Great Britain. Models of the ancient and new fortifications in Great Britain were presented to the Exhibition. No

\* In the *Force Militaire de la Grande Bretagne*, Paris, 1820, 2 vols. 4to., with atlas.

† There were two Congreves, father and son; the former introduced great improvements in the construction of artillery carriages and indicated rockets. The son (the late Sir W. Congreve), undertook to develop their construction and application.

\* This exhibitor has been awarded a Prize Medal by the Jury of Class X., in whose list his name appears.

inventions relating to the attack or defence of places have been sent in; so that we cannot speak of the merit either of officers or workmen employed in military engineering, however eminent they may be. We have, from other nations, some remarks to make on the subject of ordnance.

#### A. CANNON, AND THEIR CARRIAGES.

The articles exhibited under this head are few in number. It has, apparently, been felt, that since it is the main object of the Exhibition rather to make known the progress and to promote the arts that add to the comforts and enjoyments of life, than the powerful and destructive engines employed in war, such engines are not in place here. Thus it is that France, so capable of illustrating all that relates to this branch of the art of war, contributes nothing, nor have the public departments of Great Britain sent anything. If from other countries we have received some articles that seem to belong to military warfare, they appear to have been sent rather as samples of manufacture and of materials, than for their original merits as instruments of war.

These observations are specially applicable to the very remarkable specimens of wrought-iron guns, presented by Spain and Turkey, not as the best pieces of ordnance that can be produced, but as very extraordinary samples of energy and ingenuity of production under circumstances of necessity and difficulty, where recourse could not be had to ordinary manufactories, and where these serviceable substitutes were provided with very imperfect means.

Spain has presented three pieces of cannon. 1st, a heavy brass 9-inch howitzer, weight 6,730 lbs., 8 feet long, cast at Seville, in 1849. 2nd, a 16-pounder field howitzer, of wrought iron, in weight 535 Spanish pounds, 4 ft. 8½ inches English in length, manufactured in Biscay, in 1827, during the civil war. 3rd, a 9-inch mortar (à la Gomer), of wrought iron, in weight 475 lbs., also made in Biscay, in 1838. The second article is most worthy of notice, on account of the excellency of its materials and manufacture, though it is inferior to gun-metal, from its liability to oxidation at common temperature, and the action of the residuum of gunpowder, which is greater upon it than upon cast iron or on bronze.

Turkey has presented two wrought-iron field-guns, sufficiently light to be carried upon camels. Both these guns are forged iron damasked bars, in the manner of a gun-barrel. The execution of the work appears to be perfect, and the development of fibre upon the surface is very beautiful. Both are gold-vented; the smaller is circular in section; that of the larger is a polygon of 16 sides. They were forged at Erzeroum, in 1841, with many others, by order of Abbas Pacha, the Turkish Commander-in-Chief, after the loss of the greater part of his artillery at the battle of Nezib. They can only be regarded as a substitute, in time of necessity, for the proper material. But the skill necessary to produce the articles, and the workmanship, are remarkable.

Belgium has sent from its celebrated foundry at Liège, seven pieces of ordnance of cast iron, of the models of the following countries:—

|  | Pounder.                 | Killog. | When cast. |
|--|--------------------------|---------|------------|
| Holland —                                      | 30 of the weight of      | 2,746   | 1853       |
| Prussia —                                      | 24 „                     | 2,710   | 1849.      |
| Belgium, short                                 | 24 „                     | 900     | No date.   |
| Belgium —                                      | 12 (model of the Marine) | 1,670   | 1834       |
| Belgium —                                      | 6 „                      | 886     | 1830       |
| Belgium —                                      | 6-inch howitzer          | 520     | 1832       |
| Belgium (Epruvette mortar, cast on bed at 45°) | —                        | 198     | No date.   |

The 1st, 3rd, 5th, and 6th of these guns have been subjected to continued firing, and the number of rounds sustained by each is marked upon them, viz., the

|                                     | Rounds. |
|-------------------------------------|---------|
| 30 pounder (Holland) —              | 2,000   |
| short 24 „ (Belgium) —              | 3,549   |
| 6 „ (Belgium) —                     | 2,312   |
| After which, the vent was renewed — | 3,700   |
| „ Making in all —                   | 6,002   |
| 6-inch howitzer —                   | 2,118   |

The vents exhibit a greater or less enlargement; but there is no description of the internal figure, nor are the particulars given of the charges or rate of firing. All these pieces appear to be well manufactured, and of very good material, and they are clean from the sand, without being turned.

Prussia has presented a 6-pounder field-gun, 5½ feet long, of a new material—native cast steel, forged by the hammer, mounted on a carriage of 3 feet size, and manufactured by Mr. KRUPP, of Essen, near Dusseldorf. The merits of Mr. Krupp, and his ability in working iron and steel, are proclaimed, and will be enumerated in common with that kind of manufacture, as also his steel cuirasses; we merely mention here the remarkable beauty of the workmanship of the piece of ordnance alluded to.

Besides the above the Jury have noticed the following:—

Captain TYLKEN, R.A. (275, p. 358), has presented a series of fine models of the constructions of guns for the English service, on the scale of 1½ inch per foot, with a sea-service 13-inch mortar, a 40-inch howitzer, and 32-pounder gun, on garrison carriages, and a light 6-pounder field-gun and limber. These are all well executed, but without any novelty of construction.

MUNRO, J., Jun. (282, p. 358), two very correct and finely-finished models of a 9-pounder field-gun and limber, and a 24-pounder gun.

THE HONOURABLE EAST INDIA COMPANY (pp. 911, 912) have exhibited a series of models showing the construction of artillery used in the East Indies for siege and field service, on the scale of 1½ inch per foot. These models are well executed; but they do not appear to present any particular object of preference.

There are also several camel-guns, as well as some brass field-guns, of Indian construction, proper to illustrate the modes of Indian warfare.

The Hon. Captain FITZ MAURICK (283, p. 358) exhibits two models to illustrate his mode of pointing, applied to a carriage-gun and a mortar, by means of a horizontal endless screw, acting at the segment of a wheel.

MESRS. C. A. and T. FERGUSON (84, p. 338), of Mill Wall, Black and Gun-carriage Manufactory, two pieces of ordnance, mounted for sea-service, with particular dispositions.

#### B. SMALL ARMS.

A great number of nations have sent small arms to the Exhibition; several of them such as are used for war, but by far the greater number being for sporting purposes. Three nations are prominent for the construction of small arms, the English, the French, and the Belgians. Small arms for war and for the chase, are manufactured at Birmingham, the one with due solidity, the others with refinements of workmanship. This last class is, however, sparing of ornaments.

Liège is the Birmingham of Belgium, and has a large manufactory of both kinds of guns. The Belgians, on account of cheapness, combined with good execution, sell a great quantity of small arms to other nations, particularly to Russia.

France, for the manufacture of small arms for war, is now perhaps more advanced than any other nation. St. Etienne, the town principally employed in the manufacture of muskets, has not sent anything of consequence to the Exhibition; in this it was very wrong. Paris is the best place for the fabrication of arms; here are combined all the perfection that could be desired for precision of firing, with beauty of ornament; the ornaments are very often designed by the best artists, and are executed with remarkable delicacy. We cannot enter into the details of the merits peculiar to each of the exhibitors who presented small arms, and shall confine ourselves to saying a few words under the names of each exhibitor to whom a Medal is awarded.

#### United Kingdom.

##### Prize Medals:—

BRAZIER, J. and SON, Wolverhampton (206, p. 352). Excellent locks for best guns.

DEANE, ADAMS, and DEANE, London (223, p. 352). Double and single guns and pistols, perfectly finished.

WILLIAM GREENER, of Birmingham (59, pp. 336, 337). Guns very well made, harpoon guns, for whale fishery, &c.  
Col. P. HAWKER (205, p. 352), for improvements and perfection in punt-guns.

LANG, J., London (226, p. 354). The same merit in the fabrication of their arms.

Mr. T. E. MONTIMER, Edinburgh (267, p. 358). The same kind of arms, equally well executed.

Mr. HENRY NEGHAM, London (260, p. 358). Guns, rifles, and pistols, carefully executed.

Mr. W. PARSON, of Swaffham (270, p. 358). The same merits as the two preceding gentlemen.

REEVES, GRAVES, and REEVES, Birmingham (244, p. 355). Beautiful collection of swords and other field arms, admirably embellished.

RICHARDS, WESTLEY, & SON, Birmingham (240, p. 355). Best guns and sporting guns, of excellent quality.

W. and J. RIGNY, Dublin (236, p. 354). The same merits as Trulock.

E. TRULOCK and SON, Dublin (222, p. 353). Best guns and pistols, of good workmanship, highly ornamented and finished.

WILKINSON and SON, London (200, pp. 350-352, and illustration). Best guns and rifle pistols, of good workmanship, and swords highly ornamented and finished.

Honourable Mention has been accorded to—

THOMAS FLETCHER (255, p. 357). Guns, rifles, and pistols.

WILLIAM GRATNGER (278, p. 358). Locks for guns.

MANTON and SON (217, p. 353). Gun, rifle, and pistols.

ROBERT MOLE (248, p. 356). Swords, side-arms of all kinds, and sword-blades.

T. H. POTTS (207, p. 352). Guns, pistols, and rifles.

POWELL and SON (249, p. 356). Guns, rifles, and pistols.

TIPPING and LAWRENCE (247, p. 356). Guns, pistols, and rifles, and collection of trade arms.

WITTON and DAW (203, p. 352). Guns and rifles.

#### United States.

Honourable Mention is awarded to—

Rifles and pistols, of very good quality, by Mr. SAMUEL COLT, Hartford (321, pp. 1454, 1455, and illustration); Messrs. ROBINNS and LAWRENCE (328, p. 1456); and Mr. W. R. PALMER (347, p. 1457).

#### Austria.

Honourable Mention is awarded to—

DEUTSCHER (114, p. 1013), for a Tyrolean target rifle; and A. C. KEILNER'S NEPHEW (116, p. 1013), for pistols mounted in carved ivory stocks, with accessories.

#### Belgium.

The undermentioned are deemed worthy of the Prize Medal:—

MM. ANCON and Co., Liège (143, p. 1156). A complete and varied collection of arms, very meritorious in a manufacturing and commercial point of view.

MM. N. BERNIMOLIN and BROTHER, Liège (150, p. 1156). The same exhibition as the two former gentlemen.

M. A. JANNEN, of Brussels (139, p. 1156). Collection of sporting and ornamental guns.

M. N. C. LARDINOIS, Liège (151, p. 1156). A target rifle, of first-rate workmanship, with accessories of every kind, unusually well fitted and adjusted.

M. LEPAGE, Liège (145, p. 1156). The same exhibition.

M. N. PLONDEUR, Liège (146, p. 1156). Best guns, rifles, and pistols, of faultless manufacture.

M. RENKIN, BROTHERS, Liège (141, p. 1156). Numerous collection of sporting and ornamental guns.

M. H. TOUREY, Liège (155, p. 1156). An ornamental double gun, the master-piece of a gun-maker; guns and arms of excellent workmanship.

Honourable Mention is accorded to the following:—

FALISSE and TRAPMANN (154, p. 1156), for specimens of military fire-arms; collection of nipples.

L. MALHERBE (147, p. 1156), for collection of ornamental and sporting guns.

J. THONET (144, p. 1156), for a double gun.

J. M. TINLOT (152, p. 1156), for a double gun.

#### France.

The Prize Medal has been awarded to the following Exhibitors:—

M. BERTONNET, Paris (58, p. 1174). Sporting guns and arms, carefully executed.

M. F. CLAUDIN, Paris (1057). Best guns, rifles, and pistols, of faultless execution.

M. DEVISME (166, p. 1181). Sporting guns and arms, executed remarkably for taste and goodness of workmanship.

M. GASTINNE-RENETTE (1611, p. 125). Guns, carabines, and pistols, of very good workmanship.

M. GAUVAIN, Paris (1612, p. 1254). Pistols, admirable in form and execution; sporting guns of excellent quality.

M. H. HOULLIER BLANCHARD, Paris (1628, p. 1255). Pair of pistols, with accessories, chased and encrusted with gold, with a case richly sculptured; in boxwood, showing an extraordinary degree of perfection in workmanship.

M. LEOPOLD BERNARD, Paris (1547, p. 1250). Double and single-barrelled guns of beautiful damask, and of excellent workmanship throughout.

M. LEPAGE-MOUTIER, Paris (1364, p. 1241). Sporting guns, of excellent quality, ornamental guns of exquisite workmanship, swords and side-arms of the Duc de Luynes's damask, of remarkable novelty; bucklers and objects of art.

The under-mentioned have received Honourable Mention:—

M. F. BERGER, St. Etienne (418, p. 1198). Fancy fowling pieces, of various kinds, of excellent workmanship.

M. B. BEHRINGER, Paris (1546, p. 1250), for good fowling-pieces.

M. ALBERT BERNARD (1075, p. 1229). Excellent Damascus gun and pistol barrels.

M. DELACOUR (1582, p. 1252). Swords and sabres, imitated from various countries, &c.

M. PRELAT, Paris (1681, p. 1257). For collection of pistols, ornamented.

#### Zollverein.

Prize Medals are bestowed on the following:—

Messrs. A. and E. HOILER\*, of Solingen (637, p. 1085). Large and varied collection of swords, blades, and side-arms, of great excellence.

M. CARL AUGUST FISCHER, Lübeck (5, p. 1141). Double-barrelled rifles and fowling-pieces.

The under-noted exhibitors are Honourably Mentioned:—

SCHNITZLER and KIRSCHBAUM, Solingen (480, p. 1078). Infantry and cavalry swords, &c.

SCHMOLZ, WM., and Co., Solingen and Berlin (673, p. 1087). Collection of swords.

W. and G. PISTOR (481, p. 1078), for a rifle for carrying pointed balls.

M. C. V. HERNLEIN, Banberg, Bavaria (20, p. 1099). A rifle, curved and ornamented in the old German style.

J. A. KUCHENHAUTER (21, p. 1099), for pistols.

MM. WEBER and SCHULTHEIS, Frankfurt-on-the-Maine (6, p. 1121). Single and double-barrelled rifles.

M. I. SCHMIDT, Mecklenburg-Schwerin (2, p. 1134). Guns of good workmanship.

#### Spain.

Don E. ZULOAGA, of Madrid (264A, p. 1346), is rewarded with the Prize Medal for his fire-arms and pistols, most magnificently chased, engraved, and encrusted with gold ornaments of very graceful designs.

ROYAL MANUFACTORY of TOLEDO (266, p. 1346) is honourably noticed for sword cutlery, richly ornamented.

#### Switzerland.

M. V. SAUERBREY, of Bayle (68, pp. 1270, 1271), ob-

\* These exhibitors have been awarded Prize Medals by the Jury of Class XXI., in whose list their names appear.

tains a Prize Medal for a large rifle, mounted, fitted, and furnished in the most perfect manner.

Honourable Mention is made of—

M. JEANNERET, of Locle, Canton of Neuchâtel (5, p. 1265), for a rifle with steel barrel.

M. FISCHER, of Chur (265, p. 1283), for a double American rifle.

J. VANNOD (69, p. 1271). Target rifle.

#### C. TENTS.

A Prize Medal is given to Mr. R. EDGINGTON (302, pp. 359; 360) for the tents exhibited by him. One is 12 feet by 8, with poles 6 feet high, proposed for officers or emigrants. Another is for troops, travellers, or emigrants, 12 feet square, supported on one centre pole, like the round tent of the British service; but its figure is a pyramid, instead of being a cone. The angles are strengthened from the head of the tent by 1-inch tarred rope, to which the canvass is bolted, and which, being secured to strong pegs in the ground, constitutes the principal support of the tent. In the middle of two opposite sides a sort of porch is formed, sustained by a light 6-foot pole, giving entrance to the tent, and affording the great advantage of a thorough draught of air. It is also ventilated at the top, and the orifices secured against the entrance of rain. The centre pole, which is 9 feet 10 inches long, divides into three parts, the small ones into two, and the whole pucks into a valise 40 inches long, by about 13 inches in diameter, the weight of which is 86½ lbs. The two porches and the very complete ventilation they afford are improvements of great value, particularly for the sick, when the large hospital tents are not carried.

Mr. Edgington proposes, for military use, to employ bleached canvass, and to tan it, for preservation from mildew, a measure deserving of consideration. To his larger tent he has attached a portable stove and cooking apparatus, well adapted and arranged for the use of emigrants, but not so portable as necessary for military service.

#### D. DEFENSIVE ARMS.

A Prize Medal is given to M. FRIED KRUPP (677\*, p. 1087), of Essen, for having exhibited a cuirass of German native cast steel, the material of which is so much improved by manufacture as to attain a high degree of resistance to the balls of fire-arms, though it has not yet been determined whether this resistance exceeds that which would be afforded by cast steel made from cemented steel. M. Krupp's success, however, is deserving of reward.

### PART III.

#### MILITARY, NAVAL, AND OTHER MAPS.

This Jury has been charged with the care of examining the various kinds of maps executed in consequence of surveys made for naval, military, or geological purposes.

The Council Medal is awarded to the ADMIRALTY OF GREAT BRITAIN (p. 344), under whose superintendence and directions accurate surveys have been executed, not only of the coasts and ports of the three kingdoms, but of the coasts of the greatest part of the globe.

Drawings of great accuracy are executed, according to these surveys, by the Hydrographical Board under Admiral Beaufort. Afterwards, maps confined to the indications that are indispensable for navigation are published and sold at a very cheap rate to the officers of the merchant service.

It is understood that the Council Medal granted to the Admiralty for models and improvements in ship-building, with the combination of the forces of wind and steam,—and for the improvements of the azimuth compass,—shall be united with the same award for the eminent services rendered by the surveys, calculations, drawings, and publication of hydrographic maps, under the direction of the learned and liberal Hydrographical Department of the Admiralty.

\* This exhibition was awarded a Council Medal by the Jury of Class I., in whose list his name appears.

*French Department.*—The science and practice of hydrography owe much to France, having been brought to perfection by the celebrated Beautemps Beaupré. Hydrographic maps were undertaken from surveys made by the celebrated hydrographer, M. Beautemps Beaupré, in the time of the Emperor Napoleon, along the coast of Flanders. For thirty-five years afterwards that undertaking was continued along the French coasts of the ocean, and the Mediterranean, including Corsica and Algeria. The French survey presents the most complete description of the shores, and of the ground under water, for a great distance, with the configuration of any existing dan.

The calculations were carried on, as well as the survey, with the help of the hydrographers' staff, under the direction of M. Beautemps Beaupré, and with the utmost precision; the drawings, as well as the engravings, are worthy of this notice. It was in this way that the magnificent Atlas, or "Neptune of the Coasts of France," was produced, the finest specimens of which have been presented to the Exhibition.

The Council Medal to be delivered to the DÉPÔT GÉNÉRAL DE LA MARINE (128, p. 1177, France) in Paris, as an acknowledgment of the scientific labours evinced in the hydrographic surveys of France, and also of those of M. Beautemps Beaupré, and the engineers associated with him.

M. C. E. COLLIN (426, p. 1177), the engraver of the Hydrographic Dépôt of France, has exhibited maps in his own name, very remarkable for the skillfulness and accuracy of their execution. The Prize Medal is granted to him.

The Ordnance Department of Great Britain, having the command and direction of the scientific bodies of artillery and military engineers, was, very properly, charged with all the operations necessary for the survey, calculations, and drawings of the land map of the three kingdoms. This vast enterprise is now in a state of great forwardness, and is one of the scientific monuments most worthy of the British nation. For the copper-plate etchings, and for the use of electrotype process in reproducing the plates, our eulogium is justly due to the establishment at Southampton, where they are executed.

The Council Medal is granted to the ORDNANCE DEPARTMENT (128, pp. 341, 342), who exhibited the maps, as a just and honourable tribute to the meritorious and scientific officers of that department who prepared them.

A map of England and Wales, engraved by himself, is exhibited by Mr. CATCHLEY (74, p. 541). The map is on a scale of half an inch per mile.

The French Minister at War has presented numerous sheets of the new map of France.

The French map of Cassini was as perfect and complete as such an undertaking, by a single person, could be; this map, already more than a century old, no longer represents the superficies of a country in which such enormous changes have taken place. As early as 1816 a scientific commission, under the presidency of the illustrious Laplace, planned the undertaking of a new and improved map of France; combining the most precise astronomical observations with an accurate general triangulation. Two parallel lines were measured, the one from Brest to Hungary, through Strasbourg; the other, following upon the globe the *parallels moyen*, was carried to the south of France, and continued through Italy to Finme. These lines, accurately calculated, spread new light upon the figure of the earth.

In the French map each place of importance is given with three elements, necessary to determine its complete geometrical position, the longitude, the latitude, and the altitude above the level of the sea.

The operations were at first executed by the body of Military Geographers; but this body having been united to the Corps Royal d'État Major, they continued, under a new title, their scientific undertakings; some of them going upon the ground, each summer, and returning to the Dépôt de la Guerre, to complete the calculations, and execute the drawings.

The map of France is justly admired for the beauty of

the engraving, and the system of etching, by horizontal lines, which prevents all confusion to the eye, and gives the best idea of the form of the ground.\*

The Council Medal is granted to the *Départ de la Guerre* (804, p. 1219), in Paris, for the scientific body employed in executing the land map of France.

Austria has presented maps of Italy and of the Duchy of Austria, equal to the best of England and France. Indeed, the maps of Italy were undertaken by the French when they were possessors of that peninsula.

The Council Medal is granted to the *MILITARY GEOGRAPHICAL INSTITUTE* (363, p. 1028, Austria), Vienna, which presents the maps.

*Geological Maps.*—Some years ago, Mr. Greenough, a distinguished geologist, executed a geological map of England upon a scale not larger than that of France. Sir Henry De la Beche had the courage to undertake a new geological map upon the great scale of an inch per mile. This large size rendered it possible to add scientific information in the ordinary map, to present in great detail the nature of the stratifications, to apply his map to agricultural, metallurgical, and mining studies, and to give the delineation of the metalliferous and other veins. Sir Henry De la Beche, alone, executed the geological maps for Cornwall, Devonshire, and a part of Glamorganshire. An official *corps des mines* was subsequently created, under the direction of Sir Henry De la Beche, with the name of "Geological Survey," which directed and continued the great geological survey of the three kingdoms. Sir Henry De la Beche being the superintendent of Jury I., to whom this subject naturally belongs, the adjudication on the merits of the geological maps was transferred to Jury VIII. at our request.

The Council Medal is given to the *GEOLOGICAL SURVEY* (159, Class I., p. 137), in honour of the excellence of the work and of the staff of officers-charged with the execution of the map, under the direction of Sir Henry De la Beche.†

The geological map of France, a public undertaking, has been executed by the "*Corps National des Mines*," and we must add, principally, by two members of the Institute of France, both General Inspectors of this body, MM. Dufrenoy and Elie de Beaumont. M. Dufrenoy, one of our French Jurors, was charged with the north-easterly part, and M. Elie de Beaumont with the south-western part of France. Both employed thirteen years in exploring the ground, and four years in the labour of the cabinet, as well as in the classification of more than 30,000 specimens of minerals which they collected in their local investigations, for which they travelled more than 40,000 miles on foot.

The French geological map, executed on a scale of  $\frac{1}{500,000}$ , is an excellent reduction of the great official map of France. The Geological Society of London, considering the great importance of such a scientific undertaking, granted their quinquennial Wollaston Medal to its authors.

The Council Medal is granted to the *Ecole des Mines*, in honour of the *Corps National des Mines*, whose engineer executed the map of France.

M. DE LITHEMÉUIL, the ingenious foreman of the Lithographic National Press of France, was the inventor of the excellent process for colouring maps. He deserves the Prize Medal now granted to him.

The principal geological maps were coloured by the hand, but the *chef de la lithographie* at the National Press at Paris, has discovered so simple and ingenious a proceeding for colouring with the press, that all is done now by machine process. So perfect, indeed, is the operation, that, with a magnifying-glass, the colours are seen to follow rigorously the lines forming the limits engraved

upon the map; and in no part do the colours exceed or remain behind that limit.

DUPIN, REPORTER.

Paris, November 1851.

## APPENDIX.

### SWEDISH GUNS.\*

The articles belonging to this Class, recently sent from Sweden, comprise—

1. A cast-iron shell-gun, of 8.9 inches calibre (English), and 9 feet 6 inches long, made on the construction of Baron M. von WAHRENDORFF, to load at the breech, and mounted on a carriage and slide, also of cast iron, adapted to a casemate. The gun is in weight 9,671 lbs. Swedish (*Victualie Vigt*), or 81 cwt. 0 qr. 4 lbs. English, and is marked Aker, 1850, No. 4. The charge and weight of projectile are not stated, but the gun is understood to be intended for spherical projectiles, and is not rifled. According to English proportions, the solid shot would weigh about 94 lbs., and the shell 70 lbs.

2. A cast-iron Swedish 6-pounder field-gun, 5 feet 5½ inches long, and in weight 856 lbs. Swedish V. V., equal to 7 cwt. 0 qr. 19 lbs. English.

3. A Danish 6-pounder field-gun, also of cast iron, 5 feet 3½ inches long, and in weight 931 lbs. Swedish V. V., equal to 7 cwt. 3 qrs. 6 lbs. English.

Both these guns are from the iron-works of Aker, and bear the date of 1851.

4. Two models of 12-pounder and 6-pounder field guns, with limbers and ammunition-boxes, &c., complete, on a scale of one-eighth.

5. Lastly, the model of a 30-pounder long gun, on a carriage and slide of wood, for casemates, also on a scale of one-eighth.

*Shell-Gun.*—The chief condition on which this gun has been constructed (next to that of loading at the breech), appears to be that its recoil should be very limited, and that it should not require to be run up. It is accordingly mounted on a cast-iron carriage and slide well suited to those conditions, and of ingenious construction, traversing on a pivot placed about 18 inches in front of the head of the slide, and therefore in the throat of the embrasure. The axis of the gun is four feet from the ground, and the total length of slide from its head to its extremity (being the distance it would occupy in a casemate), is rather less than 10 feet, or from the pivot 11 feet 6 inches. The extreme breadth of carriage and slide is in front 2 feet 10½ inches, and in rear 3 feet 2 inches.

The weight of the carriage is 5,215 lbs. Swedish V. V., or 43 cwt. 2 qrs. 12 lbs. English, and that of the slide 3,537 Swedish V. V., or 29 cwt. 2 qrs. 6 lbs. English. The gun and carriage together being 124 cwt. 2 qrs. 16 lbs. English.

Though not requiring to be run up, the gun is not on a non-recoil principle, the slide being so constructed as to admit of a motion of the gun and carriage when fired, of about 3 feet 6 inches, which at first is horizontal, and then for about 3 feet on an inclination upwards of 12½°, by means of which the force of recoil (the weight moved being 5½ tons nearly) is gradually resisted and overcome. From the point to which the gun and carriage is thus raised, it descends by its own weight, and, after a few inches horizontal motion, is received by an elastic cushion, formed of sheets of birch bark, placed vertically, and therefore perpendicularly to the direction of the force, making a thickness of 9 inches. By this cushion all the remaining motion is absorbed. The angle of resistance of cast-iron on cast-iron being about 94°, and the motion of the descent ending horizontally, the impression on the cushion is rendered moderate, and all shock is avoided. The surfaces or bearing points, on which the carriage rests upon the slide, are cylindric, of about 3½ inches radius.

A carriage and slide of the same description as that exhibited, but carrying a 32-pounder gun of Baron Wahrendorff's construction, was tried at Shoebury Ness,

\* Already 145 sheets are published, 63 are in the hands of the engravers, 52 more will conclude the work; so that it will present 260 atlas sheets when complete.

† The "Museum of Practical Geology" possesses rich and unique mineral collections, furnished by the three kingdoms, and put in the most excellent order by Sir Henry De la Beche, who opened the Institution to the public shortly after the opening of the Great Exhibition.

\* The subjects introduced in this Appendix arrived after the dispersion of the Jury of Class VIII.

in 1850, with 30 rounds, at 5°, 10°, and 15°, and stood perfectly well. It is, however, probable, that the motion of so great a weight, on surfaces of very limited extent, would, in time, cause the latter to become disintegrated, and to require renewal.

Altogether the arrangement of the carriage and slide, apart from the consideration of the material, and the strong objections to it which exist, is very ingenious; but its value is obviously entirely dependant on the question to which it is subordinate—whether or not there is any advantage in loading at the breech.

On this point a very decided opinion has been formed in this country. In 1842, trials took place of two 24-pounder guns of Baron Wahrendorff's construction, similar to that exhibited before the Select Committee at Woolwich, and on board Her Majesty's ship "Excellent," at Portsmouth; the result of which was the opinion that there would be no advantage in adopting such a gun into Her Majesty's service.

More recently, in 1850, the trial above mentioned, of a 32-pounder gun of Baron Wahrendorff took place, followed by an extended trial of another 32-pounder to load at the breech, proposed by Major Cavalli, of the Sardinian Artillery, and constructed at the works of Baron Wahrendorff, in Sweden, from whose method it differs in the mode of closing the breech by a flat, instead of a cylindric plug, transverse to the axis; in being rifled, and in carrying a hollow projectile of a cylindro-conical figure of 64 lbs. weight, or double that of the round shot of the same calibre. Major Cavalli's carriage and slide, like that of Wahrendorff's, were both of iron, but differed from one another in some details not necessary here to refer to.

The views of Major Cavalli are fully explained in his "*Mémoire sur les Canons se chargeant par la culasse, et sur les Canons rayés*," published in Paris, 1849. After a long course of experiments at Shoebury Ness, in 1850, with a gun of his construction, which showed by the increase in the weight of the projectile a very considerable increase of range might be obtained, but no other material advantage, the experiment came to an end by the whole breech of the gun flying off in one piece, giving way at the passage of the transverse plug by the explosion of the charge. In reference to this result, it should be observed, that the construction of Wahrendorff has greater solidity, and is superior in strength to that of Cavalli.

The Committee, after giving the whole subject a very careful consideration, adhered to the opinion expressed in 1842 on Baron Wahrendorff's 24-pounders; and with reference to those of Major Cavalli, they came to the conclusion that guns loading at the breech cannot be considered safe, and that those in question were in their essential qualities "greatly below the ordinary guns of the service."

It appears, however, that in Sweden, Baron Wahrendorff's construction has to a certain extent been adopted; and that the fortress of the island of Waxholm, which forms one of the defences of the approach to Stockholm, is armed with guns in casemates, similar in all respects to that sent to the Exhibition.

Without doubt, then, the Swedish artillery must have become satisfied that this construction possesses advantages over that in ordinary use. Yet it is not evident in what these consist, more particularly when, apart from the question of the resistance of the material, so great a danger is always present as the possibility that the breech has not been securely closed. To ensure this operation in the heat of action must demand great care and attention, for which time is necessary; and it would seem to be requisite that it should be performed by the man who fires. Looking at all the operations to be performed, it does not appear likely that any material advantage can be gained as to rapidity of fire. And in respect to the number of men required, they cannot well (making no allowance for relief) be less than three per gun, a number which is sufficient to keep in action a gun of the ordinary construction, and of similar weight.

Upon the whole, admitting the arrangements by which Baron Wahrendorff closes and opens the bore to be most ingenious, they undoubtedly render the gun to which

they are adapted much more liable to derangement and interruption than can happen to those usually employed. And since the effect of heavy artillery depends infinitely more on *precision* than on *rapidity* of fire, it would clearly be preferable, supposing (which, however is not apparent) that there is an advantage in facility of service, to arrive at the same quantity of fire by an increase in the number of the guns, rather than to rely upon a mechanism liable to be put out of order, and that possibly may thus become fatal to those who use it.

In material, Sweden possesses advantages in the great strength and resistance in the cast iron produced from the pure and rich mineral, smelted by wood charcoal, that she employs, which no other country can command; and were we in England to attempt, with the cast iron from the coal formation, the same forms and dimensions as those employed in Sweden, we should, without doubt, encounter still more frequently the same result as attended the trial of Cavalli's gun.

This observation does not, however, in any way detract from the merit of Baron Wahrendorff's constructions sent to the Exhibition, which must be admitted to be of great ingenuity and interest; and taking it for granted that his guns have been submitted in Sweden to trials that have proved satisfactory, they solve an important problem.

Whether, however, these constructions, and that of the gun in particular on which they are dependant, are such as may be generally and advantageously applied, is another question, into which it does not seem necessary further to inquire.

No drawing or papers have been transmitted to show the construction of the casemate and embrasure in which the gun is mounted, but it may be presumed that they resemble, more or less, those of Cavalli's system.

*Iron Field-Guns.*—The Swedish and Danish cast-iron field-guns are excellent samples of those which are employed in their respective services, in which they are preferred to brass, and with good reason, so far as the more perfect preservation of the bore and consequent accuracy of fire, are concerned. The bore and vent, however, require to be carefully attended to and protected from oxidation. The weight of the Swedish gun is a hundred-weight and a few pounds more than that of the English brass light six-pounder; but the former is 54 inches longer, and the bore 16 inches larger than the English gun. The shot is consequently heavier, and the charge of 2 lbs. Swedish exceeds by 7 ounces that of the English gun. Cast-iron field-guns have been in use in the Swedish service since 1805, and recently their horse artillery, who were armed with brass guns, have exchanged them for iron.\*

There seems no reason to doubt that cast-iron field-guns of so excellent a material as Sweden produces, may in many climates replace those of brass of the same weight; but within the tropics, and where they could not receive continued attention, the action of the atmosphere and of the sea-air would render them less durable in the vent and cylinder than brass.

*Models of Swedish Field-Guns.*—These models, extremely well executed by BERGQUIST, an artist of Stockholm, exhibit in wood and iron, and in full detail, the peculiar construction of the Swedish field-artillery, as established in 1831. They show all the arrangements of the draught, and the method of attaching to the limber which gives a power of locking round, or of altering the direction of the march, of 80°. They are very deserving of attention.

*30-pounder Long Gun on a Carriage and Slide for Casemates.*—This model, by the same artist, and on the same scale of one-eighth as above, is also very well executed, but presents no mechanical feature of importance. It is on a front pivot, and has ingenious mechanism for traversing by a small wheel and winch, within the hind trucks; but this refinement is not wanted, and there is altogether a character of complexity that does not properly belong to machines for military use. The gun appears to be 10 feet 2 inches long, and the whole length of slides 14 feet 10 inches.

\* Jacobl, *Etat actuel de l'Artillerie de Campagne Suédoise*. Paris 1849.

## CLASS IX.

### REPORT ON AGRICULTURAL IMPLEMENTS.

[Her Majesty's Commissioners consented that this Report should be published in the "Journal of the Royal Agricultural Society," a Committee appointed by that body having acted as the English portion of the Jury. It accordingly appeared in the Number published in January 1852. The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE and ILLUSTRATED CATALOGUE.]

#### Jury.

P. FUREY, M.P., F.R.S., *Chairman and Reporter*, Phsey, near Farringdon.  
 Col. CHALLONER, 11 Charles Street, Berkeley Square.  
 B. T. BRANDRETH GIBBS, Half-Moon Street, Piccadilly.  
 A. HAMMOND, Westacre, Swaffham, Norfolk.  
 BYRMAN HOLSEN, Zollverein.  
 B. F. JOHNSON, United States; Secretary of New York Agricultural Society.  
 JOSEPH LOCKER, M.P., F.R.S., 6 Chester Terrace, Regent's Park.  
 C. M. LAMPSON, United States.  
 Professor HILDBERG, Austria.  
 W. MILLS, M.P., Leigh Court, near Bristol.  
 L. C. E. MOLL, France; Professor of Agriculture at Conservatory of Arts and Manufactures.  
 Baron MARTENS D'OWIN, Belgium.  
 Professor RAV, Zollverein; Professor of Political Economy.  
 J. VILLIERS SHELLEY, Marefield Park, Sussex.  
 H. S. THOMPSON, Moat Hall, near York.  
 \* Chevalier DE KLEYER, Proxy for Professor Hildeberg.

#### Associates.

Sir JOSEPH PASTON, 35 Gloucester Place, Portman Square.

In endeavouring to fulfil the command of your Royal Highness, that each Reporter should describe, as to its general state, the branch of industry which falls within his department, my task will lead me not to balance the claims of rival inventions, which are far better shown by the results of the trials given in the words of my colleagues, nor yet to portray their construction, which can hardly be conveyed in words, or even by drawings, but to state plainly, if I am able, the practical effect of agricultural machinery upon the soil or its products; and so, it may be, to further the designs of that Exhibition which your Royal Highness purposed not for a gorgeous spectacle only, but, as it has worked itself out, for a focus in which the various nations might combine and compare their scattered rays of realised knowledge.

As our implements are intended not to bring about new conditions of soil, nor to yield new products of any kind, but to do with more certainty and cheapness what had been done hitherto by employing the rude implements of former centuries, certainty and cheapness of action are evidently the standard by which their merits have to be tried, and chiefly the latter property, which forms the superiority of the spinning-jenny over the distaff, namely, economy.

The yearly shows and trials of the Royal Agricultural Society have certainly done more in England for agricultural mechanics in the last ten years than had been attempted anywhere in all former time. Yet, though the inventions are many, they may be reduced to a few simple classes: in reviewing those classes, it will be most convenient perhaps to follow the order of cultivation, beginning with the instruments of tillage, and, among these, with the plough.

#### I. INSTRUMENTS OF TILLAGE.

##### 1. Plough.

It was found about twelve years ago that in many parts of England ploughs drawn by four horses were still used, while in the same neighbourhood, or even parish, other ploughs were at work equally easy for two horses. The commonest plough, resting on a heavy galloway and wheels, had been adapted to the clay soils when those soils were the chief source of corn to the country, and had been laid down from father to son, after the heavy lands

had been widely laid down to grazing ground, and the former downs had become our principal arable land. Not only, however, did these obsolete monuments survive—it was also discovered by Mr. Handley, that the inventors of new ploughs, by rejecting the wheels as well as the galloway, had produced, especially in the north, a plough which, though fashionable under the name of swing plough, had little advantage in draught over the ancient one. It was Messrs. Ransome who furnished the modern English plough with two low wheels, and with mould-boards adapted to different soils. Messrs. Howard further improved the mould-board. The mould-board, indeed, which raising each slice of earth (furrow slice) from its flat position gradually through an upright one, lays it over half inclined on the preceding slice, is the essential acting part of the plough. It should perform this spiral transfer of a very rough material with an equal pressure both crossways and lengthways. The true shape is founded on mathematical laws, but, as in a somewhat similar case of displacement, that of water by the bow of a yacht, is doubtless best determined by actual trial. The test of perfection in the work of a plough is, that the furrow-slice shall lie, after being turned over, in a perfectly straight line, not only unbroken, but even uncracked. It is by patient attention to this point that Mr. Busby, with the aid of an excellent farmer, Mr. Outhwaite, produced the beautiful mould-boards of his prize-ploughs. This unbroken furrow-slice requires some length of mould-board; and it is urged, on the other hand, in behalf of short mould-boards, that they pulverise the soil while they turn it over. Practical farmers, however, know that to pulverise is not the immediate object of ploughing laid; but as the length of the English mould-boards surprised foreigners, it may not be useless to state a further reason for that apparently excessive length. Ours also were, in fact, made short and hollow for our new ploughs, until at one of the Royal Agricultural Society's trials all the selected ploughs were brought to a stand in attempting to work a strong clay. The cause of the failure was this: the chief resistance to the horses in ploughing proceeds not from the weight of earth moved, which is insignificant, nor, unless the ground be unusually baked, from the act of covering the earth, but from two other causes, namely, friction, and on certain soils still more from cohesion. Now, if the

soil contains sharp sand, there will be no cohesion; it will work freely off the mould-board, which will be kept bright, and the skorter its surface the less will the friction be. For such soils, therefore, as are common in Scotland short mould-boards may be the best. But most English soils contain so much clay as will adhere to and fill up the hollow of a short mould-board, so that the furrow-slice will have to work not upon an iron surface, but upon the most disadvantageous of all surfaces, one of rough loam, and the draught may thus be easily doubled by friction and cohesion together. Hence, our English mould-boards have been very properly lengthened, the more properly, I suppose, because the same soil will more often have to be worked in a moist state here than in continental Europe.\* Many of the foreign ploughs, it should be said, behaved, under all disadvantages, exceedingly well, and were, no doubt, better suited than ours for their respective localities.

Ploughing, itself, is certainly a singular instance of great skill acquired by a body of men who scarcely, as was remarked by Lord Ashburton, receive the credit due to that skill. A good ploughman will set up a pole a quarter of a mile distant or more, and keeping this mark, almost-invisible, steadily in his view, will, on land perfectly smooth, trace up to that goal, until his horses knock it down as they pass on each side, a furrow so true that no eye can detect any divergence from absolute straightness. If one saw for the first time a field of short green clover converted in a few hours into a surface of clean brown soil in regular ribs, it would be regarded as a triumph of art. I mention this, the rather because in speculative writing, the plough is sometimes depreciated, and the spade is extolled, though this very operation of preparing our wheat land could scarcely be executed at all by spade, since it is necessary that the existing sward should be perfectly buried. The caution seems more necessary, because, as we have seen in the Exhibition Building, ingenious attempts are being made at steam digging, as well as steam ploughing.

The result of the trial of ploughs will be found in the following report of Mr. Shelley.

RESULT OF TRIAL OF PLOUGHS AT PUSBY, by WILLIAM MILES, Esq., M.P., and JOHN V. SHELLEY, Esq., assisted by Mr. T. P. OUTHWAITE.

The English and Scotch ploughs, eighteen in number, were put to work in the first instance at a depth not exceeding five inches—the land a young clover-ley, in excellent condition for the trial of light-land ploughs. The ploughs consisted of nine 2-wheel, three 1-wheel, and six

\* Since the above remarks were written, I have received the subjoined report from Baron Mertens; but from my own former experience in dynamometrical trials, I am bound to say that I should not draw from a single summer trial any inference even as to the lightness of a plough in ordinary work, still less as to its capacity for general work. When land is hard and dry, cleavage is the principal element of resistance; the friction is limited, and the cohesion, of course, null. Hence our English ploughs which seemed the lightest were brought in a former trial to a dead stand on moist clay. The American ploughs are very elegant and light, but seem hardly steady enough for

wing-ploughs. The work of the 2-wheel ploughs was generally good; for the first test, not exceeding five inches, we found the following most deserving of commendation in the order in which they are placed:—

- No. 1. Ball's.
- No. 2. Howard's, marked XX.
- No. 3. Howard's, marked XXX.

The same ploughs were then put to work at a depth not less than seven inches, when we found the following did the work best in the order in which they are placed:—

- No. 1. Busby's.
- No. 2. Howard's, marked XX.
- No. 3. Howard's, marked XXX.

Ball's plough, which at five inches appeared No. 1, broke the land too much at the extra depth, owing to the formation of the mould-board pressing too heavily on the furrow. The work done by the whole of the wing-ploughs was moderate, especially that by the Scotch ploughs, which was decidedly bad. The three best ploughs, viz., Mr. Busby's, Mr. Howard's, and Mr. Ball's, were then taken to the heavy land, and were subjected to a very severe test. The work there was satisfactorily completed, and we place the ploughs according to the following order of merit:—

- No. 1. Busby's.
- No. 2. Howard's.
- No. 3. Ball's.

Mr. Howard had one plough only tried on the stiff land. The ploughs were tested as before—first, at not less than five inches deep, and then at not less than seven inches, and the same result appeared at both depths. The objection observed in the plough of Mr. Howard was, that there appeared to be too much curvature in the tail of the mould-board, which caused the land to break up in turning, and a great advantage was thus given to the plough of Mr. Busby: at the same time, the work done by Mr. Howard's plough was very good; that of Mr. Ball's good; but that of Mr. Busby's was superior.

Three 4-horse ploughs were tried in the lighter land at a depth of from nine to ten inches; they appeared on that in the following order of merit:—

- No. 1. Busby's; No. 2. Heasman's; No. 3. Howard's.
- Six subsoil ploughs exhibited:
- No. 1. Bentall's; No. 2. Grey and Sons; No. 3. Comins'; No. 4. Coleman's.

In the latter an improved system of adjusting the lever appeared, the construction of which we consider to be good.

In the turn-wrist ploughs we considered that none were exhibited deserving of remark. Lowcock's one-way plough could not be worked, owing to a portion having been lost on the railroad; but having tested it on former occasions, we recommended it as worthy of notice.

breaking up an English clover-ley. The Belgian mould-board is good, though the framework would be as unsuited to our workmen as our own would be to theirs.—P. P.

“London, July 29, 1851.

“The trial of the following prize ploughs with Bentall's dynamometer took place on the 25th instant, at Mr. Mechi's farm, near Kelvedon, Essex, before Colonel Challoner, Mr. Johnson, and myself. Morin's dynamometer (French) could not be tried, on account of the rain. The trials were attended with great success, as you will perceive by the following results:—

| Ploughs.    | Name.            | Points of Resistance. | Remarks.   |
|-------------|------------------|-----------------------|--|
| 1. Belgian  | Odours           | 527                   | Land very hard going up hill; coming down in Ball's plough's furrow. |
| 2. American | Hale and Spear   | 530                   | Land hard.   |
| 3. English  | Busby            | 540                   | Land worked well.  |
| 4. French   | Bodin            | 546                   |  |
| 5. Dutch    | Jenken           | 553                   |  |
| 6. Belgian  | Delstaenehe      | 568                   | No ploughman to use them well.                                       |
| 7. English  | Howard           | 569                   | Hard land.   |
| 8. American | Fronty and Moors | 579                   |  |
| 9. French   | Talbot           | 580                   |  |
| 10. English | Ball             | 646                   | Very hard ground; very good furrow.                                  |
| 11. English | Ransomes and May | 659                   | Very hard piece of land.   |

The best of the six Belgian ploughs exhibited was that of Mr. Oileurs, which cut the side clean and left the sole level; worked steadily, and was easy to hold. In the turn-wrist ploughs of Mr. Vaumaci, a new principle of turning at the ends of the land, and of the adjustment of the mould-board, is worthy of consideration. The turn-wrist plough of Mr. Dufour also worked satisfactorily. It is right to observe that Mr. Busby had applied to his plough the moveable nose-piece invented by Messrs. Ransome. Upon the whole, it is considered by the Judges that the working of the plough was satisfactory.

JOHN VILLIERS SHILLITY.

It should be remarked that ploughs suited for common and for deep ploughing distinctly have for some time been separately encouraged by the Royal Agricultural Society. There can be no doubt that on most soils it is useful once in four years, when the root crop recurs, to give the land a deep stirring: if that be thought too laborious, the farm should, in each field, get once at least, if only once for all, a thorough disturbance. But a common plough is not suitable for this purpose, since the soil crumbles back into the furrow. One such deep plough, therefore, as Busby's should be kept on most farms, to be worked at leisure in winter with four or even six horses.

## 2. Harrow.

The harrow has been made, I suppose, with square bars, and therefore straight-set teeth, for as many centuries as it has been used; but it is difficult to make the teeth of such a harrow work always in different cracks, although the harrows are dragged from the corner. This imperfection has been remedied within the last few years, in two harrows, to each of which prizes have been awarded. The teeth being set crosswise, the harrows themselves can now be drawn straight.

A third novelty has also been produced and rewarded—Mr. Coleman's expanding harrow. The bars at every point of crossing are united not by a screw, but by a loose pin, on which they work freely. Thus the width of the harrow can be increased or diminished, and at times, according to the state of the land, be brought nearer together or spread wider apart, exactly like the mimic soldiers on the child's toy. It is true Mr. Coleman's harrow looks rather cumbersome, but on examination it is found to possess small, almost invisible, wheels, which are easily let down, and serve to move the harrows from one field to another. This is a further advantage: for a set of common iron harrows must first be separated, and even then are troublesome enough to convey.

## 3. Rollers.

Not many years since the landlord was often asked by his tenant for some old tree to convert into a roller. The tree roller, when manufactured, had its framework loaded with rough materials to give it weight. But it soon wore and cracked, so as to produce in a year a most ungainly instrument. Sometimes the tree was manufactured into what was called a cheek-roll, that is to say, a roll without framework, but with an iron peg driven into each end, to which pegs the horse's traces were fastened. We have now very excellent rollers with iron cylinders, which last for ever; but it does seem that for rendering the soil fine their regular form has this disadvantage, that they pass so equally over small clods as merely to press, not to grind them. A more squeezing motion seems to be wanted. Mr. Claes, of Belgium, exhibited a roller intended for narrow round ridges, but which seems to possess the germ of this very squeezing motion which we require. The roller consists, in its breadth, of four separate rollers of equal size; these do not work on a fixed axle, but contain a central circle of iron, within which the common axle lies for the four rollers to play freely upon.

The common axle rests, in fact, always on the lower surface of the internal circle of the four rolls, which thus move irregularly with the freedom desired.

The roller has, however, been superseded in its function of clod-crusher by the instrument which bears that name, though we still see farmers engaged in the hope-

less attempt at breaking, by the alternate use of roller and harrow, clods which refuse to be broken. The barley crop of course suffers thereby in quality as well as in measure.

## 4. Clod-crushers. Norwegian Harrow.

Mr. CROSSKILL'S clod-crusher is well known as one of the most popular of our new inventions. Its principal use is in breaking down turnip-land which has been fed off by sheep in wet weather and afterwards baked by the sun. Notwithstanding its jagged iron teeth, it has been found, too, the best presser for young wheat in March, when the soil has been swollen and the roots thrown out by alternating frosts and thaws. Thus applied it also arrests the wireworm, and, if it wound the tender blade, the wheat tillers the better. By using it according to its intention, especially in the preparation of barley-land, we may avoid sowing on cloddy ground, or save three weeks' delay of the sowing, and in either case may gain at least one quarter of barley per acre; thus paying for our implement in the first season. Mr. Gibson's clod-crusher, now first brought out, is on a different construction, being formed of two rows of very narrow wheels, alternating with each other. Mr. Crosskill's has the defect of clogging when the soil is moist. Mr. Gibson's of pressing the ground rather tightly: it is between these two weak points that a choice must be made in selecting a clod-crusher. There is a third implement—the Norwegian, or, as it should be called, the Swedish harrow—which neither clods nor kneads, but then it will not press, and is heavier for the horses. I should not hesitate to choose the clod-crusher if I could afford only one such implement, but from experience of both in barley sowing, should be extremely sorry to be without the Swedish tool also, which has been lately much improved by lengthening its teeth, while its draught has been lightened by one horse in four.

## 5. Scarifiers, Grubbers, or Cultivators.

Numerous as are the forms of this implement, and it appears in new forms every year, its full serviceableness has certainly not been yet understood. It has been used accidentally as it were, and not upon system, whereas, if it were used upon system, I have no doubt that, important as are the American reapers, the cultivator would insure to the English farmer upon stock land advantages quite as great, if not greater, for it would save him nearly one-half of the entire labour now bestowed on his ploughing, but to prove this it will be unavoidable to enter somewhat into the detail of actual farming. Indeed, our implements must of course be judged not merely by their power of effecting a certain object, but by the usefulness of that object when it has been effected. Thus Kilby's paring plough will peel off the turf from a bowling-green as even as a web of cocoa-mat matting, yet if that were all, it might serve the gardener but would not serve the farmer. It does, however, serve the farmer, because it gives one mode of accomplishing a most valuable new process, the autumnal cleaning of wheat stubbles.

If order to prove this great saving, the ordinary course of ploughing on a common stock farm, according to the usual four-course system, must be shortly stated.

After the wheat crop, the land, being full of running couch, is ploughed in the winter, and ploughed again, with other operations, thrice more in the spring, until it appears to be clean, when the turnips are sown. In the next spring it is ploughed by many good farmers *twice* for barley, in order that the sheep-droppings may be well mixed with the soil, and so the growth of the barley be rendered regular. The third crop, clover, sown with the barley, gives a year's rest to the teams until it is broken up with one ploughing, and the fourth crop, the wheat crop, is sown. The account will stand thus:—

|           | Ploughings. |
|-----------|-------------|
| Root crop | 4           |
| Barley    | 2           |
| Clover    | 0           |
| Wheat     | 1           |

Now, it has been found that if immediately after harvest the wheat land be not ploughed, but pared at a depth of 2 inches only, the couch, the cause of so much labour, is intercepted before it has penetrated the ground, and all that future toil becomes needless. This work is done with the scarifier. The saving of labour is easily calculated, if we only compare the breadth of the scarifier, whichever it be, for there are many of them, with the breadth of the plough. Thus our ploughs make a furrow nearly nine inches wide, and are drawn by two horses. Coleman's scarifier, one of the best for hard ground, is 5 feet wide (seven times as wide), and is drawn by six horses. These three pair, therefore, will cover as much ground as seven pair at plough, and the labour, accordingly, would not be half of one ploughing. There must afterwards be one good ploughing given to lay up the land for the mellowing effect of the winter's frost. In the spring the land can be once more stirred with a wider scarifier (Biddle's, 6½ feet wide), which would go deeper, the land being looser, with four horses only. As this implement is equal in width to 8½ ploughs, four horses would thus be doing the work of sixteen. The operation will in labour be only a quarter-ploughing. There are saved, besides, in spring, infinite harrowings and rollings, which will defray the expense of drilling the turnips.

Again with regard to the barley-sowing after turnips, it used to be good farming, as I have said, to plough twice. But in order to save ammonia, it is still better to pare the land as quickly as the sheepfold is shifted. This may be done by Kilby's or Rentall's paring-plough, and may be set down as a half-ploughing. The first mellow the surface, and four horses scarifying at seed-time will make it fit for the drill. This last operation may be set down as one-third of a ploughing. We may now examine what saving of labour has been produced by this new class of implements:—

| Old System.<br>Ploughings |   | New System.<br>Ploughings. |   |
|---------------------------|---|----------------------------|---|
| Roots                     | 4 | One scarifying             | 1 |
|                           |   | One ploughing              | 1 |
| Barley                    | 2 | One do.                    | 1 |
| Clover                    | 0 | One do.                    | 1 |
| Wheat                     | 1 |                            | 1 |
| 7                         |   | 3½                         |   |

Thus it appears that cultivators will spare just one-half of the horse labour employed on the plough, doing the work, too, as well or better. Adopting the standard of economy as the test of their merit, we find that, if a ploughing be valued at 8s., they can save 7s. an acre yearly over the whole of an arable farm. And we may adopt this calculation in their favour more confidently, because by other means an equal saving of horse-work can be made at other seasons in other descriptions of work. Some exceptions to this general use of cultivators will occur of course to every farmer; but the substitution of them for the plough has long been known to many good farmers, though probably it has not as yet been carried out upon system by any one of them to its fullest extent.

These implements were not originally intended for stirring hard ground, but were gradually developed out of the harrow, which was mounted on wheels, with a view to the raising of loose couch out of ploughed ground, a use which autumnal cleaning will soon, it may be hoped, make obsolete.

Of the prize cultivators, Biddle's, by Messrs. RANSOME, is one of the oldest, and still one of the best. The width gives it great steadiness, and its leverage is good, though wearing an awkward appearance. Many attempts have been made to remove this defect, but none so successful as the simple straight levers by which the other prize scarifier, Coleman's, is lifted out of the ground. Since the trial I have used Coleman's implement, and find it superior to other wide scarifiers. For these implements have hitherto had two defects. They sometimes rise partially out of the ground, and sometimes swerve in their course; thus in each case missing a part of their

work. Hence arises often the necessity of dragging them a second time crossways over the same piece of ground. Coleman's scarifier never rises or swerves, but does its work as true as a plough, doing it therefore once for all. This is a decided advance, and greatly facilitates the substitution of the scarifier for the plough. For the mere paring of a very tight surface, however, even Coleman's may be sometimes too broad, and Rentall's narrow one is excellent for that purpose. Its long snout, like a swordfish's horn, is an ingenious device by which it is enabled to adhere to the land. This cheap implement has also received a prize as a subsoil plough; and though it be a good rule that no implement should do more than one thing, an exception must be clearly made here.

Another cheap paring plough, Kilby's, should be mentioned though not in the Exhibition, because it has the peculiar merit of turning over as well as paring the land.

In limiting, as has been done above, the number of ploughings, the new system of winter cropping has been passing over, because those extra crops, green rye or tares, winter peas or beans, would more than pay for their extra ploughing. Taking the old system simply, and working it with new tools, we see that common stock land need be ploughed twice only instead of eight times in four years—once after clover, when the green leaves must be turned down and the dung perhaps be covered in, which the plough only can do, and once, in order to stir the land deeply for root crops, and lay it rough for the winter frosts. I will venture to add what may appear theoretical—that, if ever steam be successfully employed in cultivation, it will probably be less by ploughing or digging than with an implement like one of these cultivators, because they are able to work so much wider a space as they pass long in their course. This plan of autumn-cleaning is the more valuable because it is a practice of actual farmers. When we hear of wheat being grown on alternate portions of the same field every year, such an experiment is highly interesting in a scientific view, yet we feel certain that it cannot become general; but when we know that good farmers are yearly extending the practice of autumn-cleaning upon stock land, we are assured that whatever be its advantages they will be generally available upon land of that character. From the preparation of land we may now proceed to

## II. IMPLEMENTS USED IN THE CULTIVATION OF CROPS.

### 1. Drills.

The sower with his seed-lip has almost vanished from southern England, driven out by a complicated machine, the drill, depositing the seed in rows, and drawn by several horses. Here, at least, one would suppose that there must be an increase of expense in the new operation, and, above all, an increase of horse labour; but even here there is, or may be, sometimes at least, on the contrary, a diminution. For though we observe only the one seedsman striding over the fallow, he is followed by machinery—the drags and the harrows—which, though simple enough, yet, as they repeatedly traverse the land, run up to a formidable amount the horse-work expended in this primitive method of sowing.

In Mr. Haxton's Prize Essay upon Oats, which is just published,\* we find the following passage:—

*Sowing and Harrowing.*—The general practice in Scotland is to sow oats broadcast on the winter furrow, and to cover in the seed by two, three, or four harrows coupled together and drawn by as many horses. . . . Six harrows, three and three together, and drawn by six horses and driven by two men, follow the sower, and give a double stroke in the direction of the ridges.

Three more strokes, five altogether, suffice, as Mr. Haxton informs us, on friable land, but on an old sward, the amount of horse-work expended is really wonderful.

Old tough lea or wet-ploughed land requires a far greater amount of harrowing than this to bring it into a proper tilth. Two double strokes are given in the direction of the

\* Journal of Royal Agricultural Society of England, Part xxvii., p. 126.

ridges to break the furrows and prevent the turf from being torn up by the cross harrowing; and it is seldom that the operation can be properly accomplished with less than six double strokes or twelve harrowings.\*

Thus a harrow has to be drawn twelve times over the same ground by a horse. If we imagine it to be drawn once by twelve horses, we shall see at once the vast saving which would be effected by the Woburn drill, of about the same width with the harrow, drawn by two horses only, yet burying at once most of the seed, and followed, as it has been preceded, by a light harrow—a saving of eight horses in twelve, or two horses in three. This is, however, an extreme case; but we should not be far wrong in saying that by the Woburn drill, which will come presently under our notice, two horses in four, or one-half, might be saved to the farmer who has been in the practice of broadcasting.

There is also a saving in seed by the use of the drill; but it is further interesting to observe how the drill dovetails, as it were, with our last class of implements, the scarifier. When drilling was unknown, great stress was laid upon so ploughing the land that the furrow edge would stand up sharp at the exact angle of 45 degrees, in order that the harrows catching those edges and crumbling them down might properly cover the seed. No one would have dreamed of sowing corn upon scarified land. Now, on the contrary, the surface may be perfectly smooth; and wheat may be drilled after turnips in winter upon land which has been only breast-ploughed, pared, that is, half an inch deep; for the seed, if drilled, is perfectly covered, and wheat prefers a firm bed. The drill again is indispensable for the use of many new artificial manures, distributing them by special coulters beneath the ground, and covering them with earth, that their excessive strength may not injure the seed, which is deposited above, last of all. The beautiful system of horse-hoeing depends too, of course, entirely on the use of the drill, which may be regarded as the key of the new system. We ought, then, to regard the whole as a system; not, using the drill, retain ancient courses of ploughing which were meant for the seedman, nor, on the other hand, fall short in the consequences of the drill—use it, that is, as some farmers do, but with no artificial manure, and without a horse-hoe to follow.

As to particular drills, there is the general-purpose drill, a very complete implement, capable of drilling, with or without manure, wheat, beans, and turnips at the different intervals suited to those plants respectively, from 2 feet to 7 inches. It comprehends in fact, two drills, the parts of which are substituted for each other at pleasure; yet admirable as is the implement, one may question whether, as corn seldom requires manure to be sown at the same time, it be not better to buy two drills separate, one for corn, the other for turnips. One improvement should be used with all drills as most conducive to the ease of the carter. Formerly, drills went upon one pair of wheels, but after they were made to carry a large weight of manure, it became hard work for the carter, who, in his zeal to keep the work straight, while leading the thill horse with a stick, steadied the shaft with the other hand, which was almost benumbed when he reached the end of the furrow. A fore-carriage was therefore added by Messrs. Garrett, which is under the command of the carter, who, by a lever keeps, without exertion, one wheel in the rut down which it previously passed, so that the rows must be perfectly parallel. This arrangement is the carter's friend, and the horse's friend too, as it removes a heavy load from his back. Messrs. Hornsby have since adopted, and perhaps improved on the principle,†

\* Journal of Royal Agricultural Society of England, Part xxvii., p. 126.

† Report on Drills.—Nearly twenty of these implements were selected and sent down to Fusey for trial. Messrs. Hornsby and Son had five drills: their ten-rows corn and general-purpose drill was a highly-finished and well-made machine, with a recent improvement, patented by them, of India-rubber tubes for conducting the seed down to the channel made by the coulters, which I consider a valuable improvement upon the old plan of a series of cups, made of tin, working one within the other. This drill also has

The excellence of all Messrs. Hornsby's and Garrett's drills is well known. The Woburn drill of Messrs.

another improvement, of two coulters bars, by which an equal pressure is obtained upon every coulters, and the double-action lever enables the manure to be deposited to any depth, and covered up previous to the seed being deposited. The price of this drill is 44*l*.

A ten-rows corn and seed drill, peculiarly adapted to drill corn on side hills by a highly-finished and ingenious contrivance, of extending or contracting, by means of a screw, two logs, similar to the governor of a steam-engine, attached to the side of the drill, and by which (the drill being hung by or supported on the centre) it can be regulated while in motion. It has also improved slides for regulating the quantity of seed delivered; it has the improved India-rubber tubes and coulters bars, like the former drill; also a very excellent fore steering, with a rack and pinion attached, by which it can be guided with great exactness. It did its work extremely well; and we awarded it a Council Medal.

A three-rows drop drill, which can be used either on ridges or flat ground. It is capable of depositing pulverized manure at any required distance from 10 to 18 inches, in given quantities from 10 to 50 bushels per acre. The seed can be deposited with the manure, or the manure covered up with soil and the seed delivered on the drops. The drill economizes manure, and worked very well. Price 24*l*. We awarded it a Council Medal.

A two-rows turnip drill on the ridge, which can be made into a three-rows turnip drill on the flat, for drilling turnips or mangold-wurzel seed and manure. This drill embraces a variety of improvements—the rollers being made in sections capable of being adapted to a larger or smaller ridge of the proper form to receive the seeds, and the second concave rollers follow, and leave the ridge in a perfect form. The drill is now so perfect, and did its work so well, that we awarded it a Council Medal.

Messrs. Garrett and Son exhibited their well-known general-purpose drill, with the improvement of a simple method of regulating it up as to work on the sides of hills. There is also a slide for the regulation of the feed of the manure, with an index to show the quantity delivered. Price 42*l*. This drill did its work remarkably well; and we considered it entitled to a Council Medal.

A four-rows turnip drill on the flat, embracing the improvements of the general-purpose drill, was also put to a severe test with other drills; but, upon the whole, we considered it to do its work a shade better than those brought against it, and we awarded to it a Council Medal.

A hand-harrow drill—the construction and excellent workmanship exhibited in the implement merited the unqualified approbation of the jury distributing grass-seeds broadcast in an excellent manner, by means of two compartments in the same box, that the quantities of each may be regulated as desired, the clover and rye grass being mixed in their transit to the ground. We considered it a very useful implement, and recommended it as worthy of a Council Medal.

Messrs. Ransomes and May, of Ipswich, exhibited a very well-constructed drop drill, which did its work excellently, and of a very different construction from any of the other drop drills; and, for the ingenuity of contrivance and superiority of workmanship, we awarded it a Prize Medal.

Mr Busby, of Newton-le-Willows, near Bedale, exhibited a drill which he called a ribbing drill, which is well constructed, very simple, and strong, and does its work extremely well, making a broader seam to lay the corn or seed in, which is considered by many, and especially by foreigners, as a great advantage. Price 14*l*. To which we awarded a Council Medal.

Messrs. Hensman and Son, Woburn, Bedfordshire, exhibited a self adjusting steering corn drill. This drill varies from the generality of drills, as it is drawn from the centre by whippie-trees instead of shafts; and the drill-man behind can steer or direct the drill with the greatest nicety. The corn-box of the drill is entirely self-acting, and delivers the seed equally well going either up or down hill. It is also capable of horse-hoeing, by attaching hoes to the levers, instead of the coulters share. This implement works very well, and the price from 18*l*. to 20*l*. We awarded it a Prize Medal.

M. Claes, of Belgium, exhibited a nine-rows, very simple, well-made Belgian drill. It did its work extremely well. The coulters made a broader seam to receive the corn than the generality of English drills; and the harrow which is attached to the drill covers the seed with fine

**HERRMAN and SON** has also obtained a Prize Medal, and has this peculiarity:—In all other drills the coulters, which distribute the manure or seed, hang from the carriage. In this drill the carriage rests upon the coulters, which are like the irons of skates; it may be said, indeed, to run on four pairs of skates. Hence this drill's power of penetrating hard ground, and of giving a firm bed to the wheat-seed in soft ground. Each drill coulter, however, preserves its independence as when suspended. This self-adjustment is required by the inequality of tilled ground, and is thus obtained: each pair of coulters is fixed to the end of a balance beam, these again to others, and they to a central one. Thus each coulter, in well-poised tank, gives its independent share of support.

Hence this drill is simpler in management than any other, for, resting on its own base like a plough, it is also guided from behind like a plough; and any man who can hold the stilt of a plough for a straight furrow can steer this drill with a pair of horses only and reins. Hence, too, its convenience; for if you wish to sow close up to the sheepfold, instead of ordering out a drill and four, as it were in state, you merely keep back one plough from the field.

Hitherto we have been dealing with corn drills intended generally for seed only. In endeavouring to fill up the picture of the point of development at which agricultural mechanism now stands, we come next to turnip drills, in which manure is also distributed as well as seed, generally bones or superphosphate. As is well known, there are two ways of growing turnips, the ridge and the flat. In the ridge, or Northumberland method, the ground is thrown into ridges by a two-sided plough, "a double Tom," and, dung being laid in the intervals, the ridges are split, and the new ridges enfold the dung.

It is on these ridges that Mr. HONNIST's prize drill works, depositing manure-dust and seed, and reducing the ridge, by concave rollers, to a compact rounded form.

The ridge system, however, is most at home under our cool northern and moist western skies—in Northumberland and in Lancashire. In our drier districts, as in Lincolnshire and Berkshire, it is found better with the bulk of the crop, when rain does come, to make more expedition. Using a turnip drill, therefore, 6 feet wide, we sow four rows at once with some light manure, and are thus enabled to sweep rapidly over our ground, while the seed finds a moist bed fit for germination before the dust begins once more to fly.

Still, however rapid the four-row turnip-drill, south-country farmers are often obliged to wait in July for a soaking shower—waiting, indeed, often in vain, until it is too late to look for a bulky turnip crop. A south-country farmer, Mr. CHANDLER, of Market Lavington, Wilts, has produced a machine to deal even with this defect of our climate. His water-drill pours down each manure coulter the requisite amount of fluid, mixed with powdered manure, and thus brings up the plant from a mere bed of dust. Having used it largely during three years, I may testify to its excellence. Only last July, when my bailiff had ceased turnip-sowing on account of the drought, by directing the use of the water-drill, I obtained from this later sowing an earlier and a better show of young plants than from the former one with the dust-drill. Nor is

earth as soon as it is dropped. There is no part of this drill likely to be out of order: it can be worked with one horse; and there appears no part of it that, in case of accident, could not be repaired by a common blacksmith. **Prize 1st.** In consequence of its combined merits, simplicity and cheapness, we awarded it a Prize Medal.

**Liquid-manure Distributor.**—Mr. T. R. Reeves and Mr. J. Bratton, of Westbury, exhibited a liquid-manure distributor, which did its work in an extraordinary manner, distributing equally manure-water or the thickest sewerage in the most perfect manner. From the construction of the machine, it is impossible to clog in the delivery of the thickest slush. It consists of a series of buckets or troughs that are attached to a metal chain or band, and which works round two rollers as the cart goes on, the wheel giving the motive power to the rollers. The price of this admirable water-cart is complete, is 16l. We awarded it a Prize Medal. —C. B. CATALAN.

there any increase of expense, if water be within a moderate distance, for we do not use powder-manures alone. They must be mixed with ashes that they may be diffused in the soil. Now, the expense and labour of supplying these ashes are equal to the cost of fetching mere water; and, apart from any want of rain, it is found that this method of moist diffusion, dissolving, instead of mingling only, the superphosphate, quickens its action even upon damp ground, and makes a little of it go further.

There is yet one more kind of drill. The common drills economize manure by concentrating it in lines along the rows of the turnip plants. Thus, instead of shovelling bones from carts, as was first done in Lincolnshire, at sixty bushels per acre, we came to sow only sixteen bushels of bones in lines, or more recently but three bushels perhaps of superphosphate, prepared either from bones or from the animal remains of geological ages, among which Liebig told us, and told us truly, to search for our phosphorus. But though turnips are sown in lines, and come up thickly in lines, no sooner are the thriving young plants well marshalled in green array than nineteen in twenty are ruthlessly cut down by the hoe, so that the field appears for a time once more bare. The roots must, of course, be allowed ample room in the row, but some manure will have been wasted in nourishing the plants doomed to perish. Hence, Mr. HORSHY's drop-drill, avoiding this wholesale massacre, is made to drop the seed and the manure, by a second step of mechanic frugality, only at those points in the lines where the plants are intended to stand. Nor are these points in the lines fixed points, for their distance can be varied from 9 inches to 18 inches asunder, and the intervals between the rows can be equally varied from 15 to 30 inches. The dose, again, of mixed manure can be varied from ten to fifty bushels per acre. Such is the elastic, yet accurate pliability, with which in agriculture mechanism has seconded chemistry. Having now gone through the various kinds of drills—corn or turnip drills, ridge or flat drills, dry or wet, line or drop drills—we may pass to a kindred but entirely new class of implement.

## 2. The Top-dresser, or Manure Distributor.

Although, as has been said, wheat is seldom sown with the manure-drill, being usually provided with its chief requisite, nitrogen, through farm-yard dung or through sheepfolding, no plant is so liable as wheat to break down from its first promise; and on inferior soils, whether too light or too heavy, one might almost say that wheat always looks well before Christmas, and always looks ill before Lady-day. Our predecessors, to refresh its flagging strength, used to spread soot or pigeon's dung, both containing ammonia, over it, especially on the lower sides of the ridges near the water-furrow, where the plant was perhaps almost killed by the lodgment of rain. But their practice was, of course, limited by resources so narrow. We, having guano and nitrate, can deal out liberally the timely supply. But if sown by hand, these very light manures, especially guano, are carried away before their descent by a strong wind; and sometimes when half a gale has been blowing, it has seemed to me that I was manuring my neighbour's field quite as much as my own. A manure-distributor was therefore required; and the agricultural meeting at Exeter brought out eight competitors, the winner being Mr. HOLMES's, of Norwich.

I rejoice to find that we have not only a good invention here, but that it is being actively used. The machine, new as it is, and involving a new outlay for artificial manure, is employed very largely in the western division of Norfolk—the classic ground of improvement—for distributing a small quantity, such as three bushels per acre, of guano or nitrate of soda, or a larger quantity of superphosphate and rape-cake, on wheat in the spring of the year. This fact deserves the more to be known, because the convincing argument for any agricultural change is that it has become a practice somewhere or other—an argument that answers where reasoning fails. The other argument—that, namely, founded on quick return—is also not wanting, as it has lately been shown that nitrate so applied on poor land will sometimes yield double its own value,—nearly a quarter of wheat at a cost of 30s. per acre.

It is curious, indeed, that this very cheap and simple machine is on some soils superceding the more costly and intricate drill. In the words of Mr. Holmes, its inventor,—

They were used very much last turnip-sowing season, and considerably more this season, for sowing manure (rape-cake, malt-comb, and guano, about 8 or 10 bushels per acre, and in some instances as much as 20 bushels to the acre, when a quantity of burnt earth or ashes are mixed) into the furrows of the ridged turnip-land, at 24, 26, and 27 inches apart. The ridges are then turned over on to the manure by the double-breasted plough, and the manure is covered sufficiently out of the way of the seed, although distributed equally around, so that, instead of striking immediately into the whole body of manure—as is the case when drilled in with the manure—it catches it gradually in its different stages of growth.

This plan proved highly satisfactory to all those who tried it last season, which has induced many others to pursue the same course this season, not only as regards the crops themselves, but also in the labour required to put the crop in. Our manure distributor will cover 3 or 4 furrows at 27 inches apart, if required, and is worked with one horse. It is followed by a light drill expressly for turnips and mangold-wurzel, which is also worked by one horse. Thus it will be readily seen that a great saving of horse-labour was effected by the use of the distributor in the place of the drill.

This saving of horse-work is indeed great; but it must not be disguised that there is inconsistency between the principle of general diffusion here recommended, and the concentration which is the aim of the drop-drill. Each method, in fact, has its merits for different purposes,—concentration for pushing the young plant, extension for feeding it in its later stages. The question, like many others, must be decided by longer experience; but the most perfect method would probably be the combination of both plans. To return to our present subject, the young growing wheat, it may not only be revived in spring by additional food, but is usually, on light land, settled down in its bed by

### 3. Press-rolls.

On some soils, especially the calcareous, the ground alternately frozen and thawed in winter throws the roots of the wheat plant almost out on the surface. For this mischief and that of the wireworm, flocks of sheep were once driven over the wheat; but we have long had the well-known wheel-roll, and, as has been said, Crosskill's clod-crusher is a still better presser when it can be used, but is not a perfect substitute, as it requires the land to be drier. The new clod-crusher, however (Gibson's), must serve, I suppose, for both purposes equally well.

### 4. Horse-hoes.

Machinery can do but one thing more for the growing crop. The hoe not only clears away a host of young weeds, but, by loosening the crusted surface, admits the air, and stimulates the growth of the true crop. Even vineyards are thus found to be relieved during long drought, and hence it is said that iron should be always between the rows of our root-crops. Ridged root-crops have been long hoed by a single horse, one row at a time. Garrett's horse-hoe cleans four rows at once of turnips, six of beans, nine of wheat. To hoe wheat thus is a delicate operation: to hoe even turnips so, when their lines are but just distinguishable, or again, when the leaves almost meet, requires not only a first-rate implement, but a steady hand and cool head to steer it. This tool will stand well the test of economy, for it will go over ten acres a-day easily, with two horses (sometimes one), a man, and a boy, at a cost of, say 10s. The work could certainly not be done otherwise for less than 2s. an acre, 30s. altogether, even if you could find hands to do it, in harvest-time. This estimate accords, I find, with the report of the Judges at the York Meeting, practical farmers, who thus speak of the implement:—"The work done by it is far superior to any hand-hoeing: it can also be done for less than half the cost: indeed, so highly do we value it, that we think no farmer can farm as he ought without it." The crops, after hoeing, soon cover the

ground, and are thus beyond man's interference until time, the ripener, summon him to the operations of harvest.

## III. HARVESTING IMPLEMENTS.

### 1. Reaping-Machine.

At the opening of this century it was thought that a successful reaping-machine had been invented; and a reward was voted by Parliament to its author. The machine was employed here and abroad, but from its intricacy, fell into disuse. Another has been lately devised in one of our colonies, which cuts off the heads of the corn, but leaves the straw standing, a fatal defect in an old-settled country, where the growth of corn is forced by the application of dung. Our farmers may well, therefore, have been astonished by an American implement which not only reaped their wheat, but performed the work with the neatness and certainty of an old and perfect machine. Its novelty of action reminded one of seeing the first engine run on the Liverpool and Manchester Railway in 1830. Its perfection depended on its being new only in England, but in America the result of repeated disappointments and untired perseverance. The United States' Patent Commissioner says of Mr. McCormick's Reaper—

In agriculture it is, in my view, as important, as a labour-saving device, as the spinning-jenny and power-loom in manufactures. It is one of those great and valuable inventions which commence a new era in the progress of improvement, and whose beneficial influence is felt in all coming time.

Besides difficulties common to all inventions, the machine could be tested but for two or three weeks in each year. When a defect was discovered, before the remedy was applied to the instrument the harvest was over, and the new form had to wait a whole year for its trial, when some fresh failure, required a fresh year's postponement of final success. It seems right to put on record Mr. McCormick's own account of his progress, or some extracts at least from a statement written by him at my request:—

My father was a farmer in the county of Rockbridge, State of Virginia, United States. He made an experiment in cutting grain, in the year 1816, by a number of cylinders standing perpendicularly. Another experiment of the same kind was made by my father in the harvest of 1831, which satisfied my father to abandon it. Thereupon my attention was directed to the subject, and the same harvest I invented and put in operation, in cutting into oats, on the farm of John Steele, adjoining my father's, those parts of my present reaper called the platform for receiving the corn, a straight blade taking effect on the corn, supported by stationary fingers over the edge, and a reel to gather the corn, which last, however, I found had been used before, though not in the same combination.

Although these parts constituted the foundation of the present machine, I found in practice innumerable difficulties, being limited also to a few weeks in each year, during the harvest, for experimenting, so that my first patent for the reaper was granted June 24th, 1834. During this interval I was often advised by my father and family to abandon it and pursue my regular business, as likely to be more profitable, he having given me a farm. No machines were sold until 1840, and I may say that they were not of much practical value until the improvements of my second patent, 1846.

These improvements consist in reversing the angle of the sickle-teeth alternately—the improved form of the fingers to hold up the corn, &c.—an iron case to preserve the sickle from clogging—and a better mode of separating the standing corn to be cut. Up to this period nothing but loss of time and money resulted from my efforts. The sale has since steadily increased, and is now more than a thousand yearly.

One merit of the machine consists in the extreme simplicity of its cutting part—a straight saw, vibrating rapidly right and left. The teeth, however, incline alternately in each direction, so that at each vibration half of them are inclined in the direction of the motion, as is shown in the diagram of a portion of the saw.

As to the practical working of the Reaper, two horses drew it at the trial very easily round the outside of the

is experienced in high carts when going up or down hill. It also diminishes the danger of an upset in rough ground or on a hill-side. So long, however, as the shafts of carts were attached in the ordinary way, it was found that when carts were much lowered, a standing direction was given to the shafts, which caused a toy load to slide backwards; and this tendency it was scarcely possible to counteract when going up a steep hill. The mode of attaching the shafts observed in Busby's cart, viz., of fixing them to the side, very much diminishes this difficulty; as, when once the plan is abandoned of making the shafts a prolongation of the axle, their position is no longer dependent on that of the body of the cart, but may be varied to suit the objects for which it is built, or the size of the horses employed by the owner. By this arrangement for preserving in a great measure the horizontal position of the shafts in carts with low bodies, together with the form of harvest frame pointed out above, these carts are enabled to carry corn or hay with as great safety as any four-wheeled vehicles; and this point being once established, it is clear that there is no longer any necessity for incurring the expense of having waggons or carts expressly for harvest purposes, as the ease and quickness with which single-horse carts can be worked more than make up for the additional load carried by waggons. On the whole, the principles of construction of Mr. Busby's cart are considered more correct than those of any other in the Exhibition, and he has made great advances towards the production of a good cart-of-all-work. His cart has therefore received the distinction of being named in the award of the Council Medal; but it should be borne in mind that the medal is awarded to the improved principle of construction, and that it is not intended to stamp this cart as a model in respect of shape, size, and other points of secondary importance, which may be varied to suit the taste or the wants of the purchaser.

2. Crosskill's wheels are deserving of notice, being made by machinery, and accurately fitted. His operations being conducted on a large scale, he is enabled to furnish them at a moderate price.

3. The cart made by the Messrs. Gray, of Uddingston, near Glasgow, has been awarded a medal, though it is considered too high, and that the navies are unnecessarily loaded with iron. The wheels, also, are too much out of the perpendicular, showing that the arms are bent, and their under surfaces not horizontal. As this determines whether the weight of a cart, and consequently of the load, shall rest on a level bed or an inclined plane, it is a point of importance. The deviation in this instance is small; but as it is a fault which a few years back was almost universal, and was in many cases carried to a very mischievous extent, no opportunity should be lost of calling attention to it wherever it is observed. Having thus pointed out what are considered to be the faults of Mr. Gray's cart (the same may be said of the Scotch carts as a class), it is but justice to him to point out that in many respects it is deserving of great praise. The Scotch iron-work is notoriously excellent, and in Mr. Gray's case it is just what it should be, substantial and well finished, and (with the slight exception above mentioned) with nothing redundant. It is also due to the Scotch wheelwrights to bear in mind that during the dark ages of English agriculture, when it was scarcely possible to meet with even a tolerably well-made cart in the central or southern parts of Great Britain, and when there seemed to be a rivalry amongst implement makers which could pile up the largest amount of unnecessary wood and iron in the form of a waggon, the Scotch carts universally retained their compact form and workmanlike character; and from being used by improving farmers in various parts of England, tended very much to originate this reform in carts and waggons which is now making such rapid progress.

Waggons.—It is difficult to conceive why use of the waggons is still retained in particular districts, unless for the purpose of wearing out what has been already paid for, and cannot be disposed of without a great sacrifice. The fact that those who use waggons are also obliged to have carts for leading manure, root crops, &c., ought to decide the question, inasmuch as it necessarily follows that a double amount of capital is required in the first instance, and greater expense sustained ever after in repairs, renewals, and providing house-room for this unnecessary number of wheel-carriages. On a large farm it is certainly convenient to have a waggon for the removal of poles, furniture, or other bulky articles; but these are exceptional cases, and the ordinary routine of farm-work can be at least as well carried on by single-horse carts or waggons. This has been proved on several different occasions by experimental trials, undertaken by the respective advocates of the two different vehicles; for the

express purpose of deciding the point. The great necessity at present existing for the introduction of every practicable economy will doubtless eventually substitute eight carts for waggons, and in the meanwhile something would be gained by introducing light, cheap, pole-waggons in the place of the cumbrous shaft-waggons which are too frequently met with.

Mr. Crosskill's waggon was considered a very good specimen of an improved waggon, being light, low, and cheap (price £61., including both pole and shafts). The advantages of a pole over shafts are, that horses can draw a greater weight when yoked abreast than at length; that two horses share the load down hill which is frequently injuriously heavy for one; and that the team can turn in less room, and is altogether more manageable.—H. S. THOMSON.

Mr. Busby, it will be observed, by placing his shafts on the side of the cart, has lowered his cart. He has lowered it as much as one in four, thereby diminishing the toil of filling carts with dung, stones, earth, &c., to the amount of one quarter. If we calculate how many thousand arms are employed in this way throughout England for many weeks in the year, we shall find that this improvement, simple as it is, will save no small aggregate amount of misapplied strength to the country at large.

Having gone through the three classes of implements with which the land is first prepared, the crops next cultivated, and the grain afterwards harvested—and having found them to stand well the test of economy by which all machines must be tried—we have now to examine the fourth, by which the corn is lastly made ready for market.

#### IV. PREPARATION FOR MARKET.

##### 1. Moveable Steam-engines.

Every visitor of the agricultural department must have been struck with the little steam-engines, which, though of pigmy dimensions if compared with the great railway racers, showed the same compactness of form and the same disposition to work. They connected the ruder tools of husbandry with machinery fitted for more intricate ends, and showed palpably that agriculture had not kept aloof from the spreading dominion of steam. Fixed steam-engines have been long used in Northumberland and East Lothian, in which spirited counties every farm has its tall chimney. These moveable steam-engines have been called forth by the Royal Agricultural Society within the last ten years, and appear preferable in general to the fixed engines, for the following reasons:—

If a farm be a large one, and especially if, as is often the case, it be of an irregular shape, there is great waste of labour for horses and men in bringing home all the corn in the straw to one point, and in again carrying out the dung to a distance of perhaps two or three miles. It is therefore common, and should be general, to have a second outlying yard. This accommodation cannot be reconciled with a fixed engine.

If the farm be of a moderate size, it will hardly—and if small will certainly not—bear the expense of a fixed engine: there would be waste of capital in multiplying fixed engines to be worked but a few days in a year. It is now common, therefore, in some counties, for a man to invest a small capital in a moveable engine, and earn his livelihood by letting it out to the farmer.

But there is a further advantage in these moveable engines, little, I believe, if at all known. Hitherto corn has been threshed under cover in barns; but with these engines and the improved threshing-machines we can thresh the rick in the open air at once as it stands. It will be said, How can you thresh out of doors on a wet day? The answer is simple. Neither can you move your rick into your barn on a wet day; and so rapid is the work of the new threshing-machines, that it takes no more time to thresh the corn than to move it. Open-air threshing is also far pleasanter and healthier for the labourers, their lungs not being choked with dust, as under cover they are; and there is, of course, a saving of labour to the tenant not inconsiderable; but when these moveable steam-engines have spread generally, there will arise an equally important saving to the landlord in

buildings. Instead of three or more barns clustering round the homestead, one or other in constant want of repair, a single building will suffice for dressing corn and for chaff-cutting. The very barn-floors saved will be no insignificant item. Now that buildings are required for new purposes, we must, if we can, retrench those buildings whose objects are obsolete. Open-air threshing may appear visionary; but it is quite common with the new machinery; nor would any one perform the tedious manœuvre of setting horses and men to pull down a rick, place it on carts, and build it up again in the barn, who had once tried the simple plan of pitching the sheaves at once into the threshing-machine. These moveable steam-engines have been gradually improved by the yearly trials of the Agricultural Society. It will be seen by Mr. Carr's Report\* that such yearly trials are still needed, as the worst of those exhibited consumes three times more coal than the best. Mr. Locke, M.P., whose engineering experience gives weight to his judgment, thinks that in other respects, too, they might be still further improved:—

To P. PUSEY, Esq., M.P.

London, 11, Adam-street, Adelphi,  
July, 1851.

DEAR SIR,

The detailed report of Mr. Carr, of the results of the experiments made on the portable steam-engines, has already been presented to the Jury over which you preside; and as you desired from me a short statement of my views of Mr. Carr's report, I beg to send you the following:—

You will find in the tabular statement of the consumption of fuel, that the several makers stand in the following order of excellence:—

|                                   | Per horse-power. |
|-----------------------------------|------------------|
| Messrs. Hornsby and Sons - - -    | 6.79 lbs.        |
| " Tuxford and Sons - - -          | 7.46 "           |
| " Clayton, Shuttleworth and Co. - | 8.63 "           |
| " Barrett, Exall, and Andrews -   | 9.20 "           |
| " Garrett and Sons - - -          | 11.65 "          |

\* The mode of ascertaining the amount of duty done and weight of coal consumed, in a given time by each engine, was the same as that adopted by the Royal Agricultural Society of England, at their Annual Show of Implements and Machinery; and the dynamometer used for the trial was the same as the one supplied to that Society by Messrs. Easton and Amos, their consulting engineers.

Messrs. Tuxford and Sons presented the novelty of placing their cylinder and working parts in a wrought-iron box at the end of the boiler, having a pair of doors to lock the whole up when not in work, which I certainly think a good idea, and of some practical importance. But to gain this, the tubes at the smoke-box end were rendered difficult to be got at. There were two engines brought to the trial-yard upon this construction, one a 6-horse direct-action upright cylinder, the other a 4-horse oscillating; but the former worked out the most duty with the least fuel.

Messrs. Hornsby and Son were distinguished by placing their cylinder inside the upper part of the fire-box, the whole of which, together with the rest of their boiler, was carefully felted and lugged with wood; and they had a well-constructed water-heating apparatus in their smoke-box, which also helped to produce the satisfactory result of great economy in fuel.

Messrs. Garrett and Son, in their engine, had made a great effort to combine lightness with strength, having substituted wrought for cast iron in the bearing for crank-shaft and other parts. Their boiler presented a great amount of heating surface, but the fire-box, to insure greater strength and a less amount of flat surface exposed to steam pressure, was made partially oval, and considerably smaller than most of its competitors. The fire-box being above the level of many of the tubes of the boiler, and the flame having to descend over a bridge, the manufacturers expressed themselves quite aware that this construction of fire-box would prevent their standing quite so well as some with respect to fuel consumed, but considered that superior strength, lightness, and portability would more than compensate, this class of engine seldom working more than a few months in the year, and having to be conveyed from farm to farm. And I certainly considered this engine the most portable, for its power, of any exhibited. During the trial some derangement took place in the slide, so that the result was not so favourable; but upon the engine being put through a second trial with Messrs. Clayton, Shuttleworth, and Co.'s, to test the comparative strength of the

In a subsequent trial, however, made to test the strength of Llangenneck coal with Messrs. Shuttleworth's engine, it appears that both engines burnt precisely the same amount of fuel; and Mr. Carr has deduced from this circumstance, that, but for some accidental derangement in the slide, in the main tabulated experiments the consumption of Messrs. Garrett's engine, which was 11.65 lbs. per horse-power, would not have been more than Messrs. Shuttleworth's, or 8.63 lbs. per horse-power.

This mode of reasoning is, I think, liable to objection; and I allude to it with a view of preventing an undue importance being attached to it. Besides, I do not entirely concur in the remarks made by Mr. Carr on the construction of these two engines.

Messrs. Garrett's fire-box is, in my opinion, decidedly inferior to Barrett, Exall, and Co.'s; and the workmanship generally is not superior. It is lighter, and so far it is better; but whether the smallness of the fire-box, to avoid weight, may not entail other disadvantages, is a question on which a doubt may fairly arise.

As regards the engine of "Ransomes and May," which, from some accidental defect, did not go through a trial, I would beg to say, that in point of workmanship it is equal, if not superior, to any of the engines tried. I think the connecting-rod might be lengthened with advantage, but in other respects it is, I think, a good, serviceable engine. As regards the other engines, I agree entirely with the remarks made by Mr. Carr. If I might be permitted to suggest a little advice to the makers of these engines, I would beg of them to attend more to the proportions of the various working parts, and less to external ornament. There is a want of good proportion in several of the engines; and this, to a mechanic of an economical farmer, is of more importance than a profusion of brass.

JOSEPH LOCKE.

Much progress, however, has been made, as our best engine now consumes less than 8 lbs. of coal per hour per horse-power; whereas an engine made by the winning manufacturer of four years ago consumed 28 lbs., that is, four times as much fuel for the same work.

Llangenneck and Newcastle coals, she worked out to a decimal the same number of pounds of coal burnt per horse-power per hour as her competitor, which, allowing for the proved difference in the strength of the coal in favour of the Welsh, would have given Messrs. Garrett 8.63 lbs. of that coal burnt per horse-power per hour instead of 11.65, as shown in the tabular statement; which more favourable result I think them quite entitled to, as the derangement in the slide was purely accidental.

Messrs. Clayton and Co.'s engine was exceedingly simple, and worked well; the governors had perfect control during the trial, which was passed through with great steadiness and credit to the makers.

As regards the other engines, I will proceed to notice them in the order as tested:—

Messrs. Hensman and Son's 4-horse, of moderate workmanship, was evidently the production of a novice. The boiler was too small for the power, and the consumption of fuel more than as much again as most of the first-class engines.

Mr. Butlin's 4½-horse: workmanship moderate; arrangement of working parts simple; and duty done for coal consumed fair when compared with others of its class.

Mr. Cabor's 9-horse: workmanship moderate; arrangement of engine ill designed; and entire weight far too great to be generally suitable for a portable engine. The boiler being a large one, with considerable heating surface, the duty done was comparatively good.

Messrs. Barrett, Exall, and Andrews' 4½-horse: workmanship moderate. The cylinder and crank-shaft bearing in this engine were placed upon the same base-plate, which was bolted to the boiler, an arrangement giving superior strength and steadiness in working. These makers adopted a link motion, controlling the slide-valve and worked in connexion with the governor, which we think a very needless complication, and worked very unsteadily. The boiler was large for the size of the engine, and the duty done for coal consumed was more nearly approaching its first-class competitors; so that, as a whole, I cannot speak less than favourably of the engine.

Mr. Burrell's 6-horse: workmanship fair, and arrangement of working parts simple and good, and consumption of fuel comparatively moderate; and that in this case also I must report favourably.

Messrs. Roe and Hanson, Strand, London's 4-horse: workmanship very inferior; general arrangement ill-designed

2. *Threshing-machine.*

This is the most complicated agricultural machine in general use; but, though it has also been long in use, and though repeated trials have been made of competing threshing-machines at our great agricultural show, it was not till the Norwich Meeting in 1849 that a very singular discovery was made of their great imperfection. It occurred to the consulting engineer, Mr. Amos, that the draught of the common threshing-machine worked by horses, should be tested when empty; and it was ascertained that some of the best 4-horse machines required no less than three horses, putting out their strength as when at plough, to keep the machinery in motion without threshing at all. In other words, of the four horses dragging round in their weary circle, three were overcoming the resistance of the machinery; one only was threshing the corn. Technically speaking, the duty performed was 25 per cent. only. So little, too, had the makers studied the principle of construction, that this enormous waste of power was capriciously divided between the barn-works and horse-works. To quote Mr. Thompson, of Moat Hall, whose reports always show that he has mastered his subject—"The machines of Messrs. GARRETT and WOODS furnish an excellent illustration of this point, the whole friction being in these cases 2.78 and 2.81—all but identical; the friction of the barn-works being, however, 2.07 and .46, while that of the horse-works was .71 and 2.35." Thus the makers were working so much in the dark, that, if the two best of the correlative parts had been put together, one horse in the four would have overcome the resistance, and the duty of 75 per cent. would have been achieved; but if unfortunately the two worst had been mated, the resistance of the 4-horse machine would have amounted to four horses and a half before any corn was put in for threshing, and there would have been no duty at all.

The same rigid trial was applied to the threshing-machines shown at Exeter in the following year. It then appeared that Messrs. Garfett had profited by the lesson, and reduced their dead resistance from 2½ to 1½, or one-half. Yet there was still found a vast difference in the power required by the competing machines. For threshing 100 sheaves in a minute, the two extremes of power required were as 14½ and 36; and the work of the machine which required triple power was inferior to that of

and clumsy; and cast iron used freely in the place of wrought. The coal consumed for duty done was three times that of the best engines.

Messrs. Ransomes and May brought an engine to the trial-yard, but from some cause it could not be made to work. It was a trunk engine, which, in so small a power as 5-horse, would give rise to much extra friction.

the machine which required least power. This short summary of what has been done already seemed necessary in order to show the interest attaching to the following report by Mr. Thompson of the trial in the third year for the present occasion:—

1. Threshing-machines may be divided into two classes—those adapted for steam or water power, and those intended to be worked by horses. In the trial of the latter it is clearly desirable that the horse-works should be tested, and on this occasion, in the absence of the ingenious apparatus invented by Mr. C. E. Amos, of the Groves, Southwark, for this purpose, repeated attempts were made to obtain a satisfactory trial by the use of the dynamometer or draught gauge. But after various methods had been fairly tried, it became evident that the results obtained were not sufficiently accurate to warrant their being made public, and the trial of the horse-works was abandoned, and the whole attention of those who conducted the trials devoted to the more important part of the machines, known as the barn-works. The accompanying tabular form shows the results obtained, which were arrived at in the following way:—

The steam-engine selected to drive the threshing-machines was itself tested to ascertain the net pressure of steam which represented one-horse power. An apparatus was then attached to it, which registered on a counter the revolutions of the driving-pulley. As each machine was brought up for trial, the maker was asked how many horse-power he required, what number of revolutions per minute he wished the drum to make, and the exact dimensions of the driving-pulley. From these data a calculation was made of the pressure of steam required in each case, and the supply of steam in the boiler of the driving-engine was so adjusted that the calculated pressure was maintained during the trial.

On reference to the tabular statement, it will be observed that col. 1 gives the "nominal horse-power," as stated by the makers; col. 2 gives the horse-power corresponding to the power of steam actually employed during the trial. The figures in these columns are for the most part identical, it being wished that the machines should be tried in accordance with their designation—i.e., that a 4-horse machine should be worked by steam of 4-horse power, &c. Some of the machines, however, could not be worked without additional power, which is recorded against them in col. 2. In col. 3 are given the revolutions made by the driving-engine whilst threshing the allotted quantity of wheatsheaves, viz., 2½ cwt. Col. 4 shows the net pressure of steam at which each machine was worked, and which had been previously calculated from the data above mentioned. Col. 5 shows

At the close of the trials, two engines, viz., Messrs. Garfett's and Messrs. Clayton's, were put through a second trial, to test the difference in steam-generating power between the Liangenneck coal used in these trials and the best Newcastle, when the difference in favour of the former was found to be as 8.63 to 11.3 lbs. of coal burnt per horse-power per hour.

TABULAR STATEMENT OF RESULTS.

| Names of Manufacturers.               | Nominal Horse-power. | Time getting up Steam. | Coal used in getting up Steam. | Coal burnt per Horse-power per Hour. |
|---------------------------------------|----------------------|------------------------|--------------------------------|--------------------------------------|
|                                       |                      | Minutes.               | lbs.                           | lbs.                                 |
| Tuxford and Sons, No. 1               | 6                    | 53                     | 50.68                          | 7.40                                 |
| Ditto ditto, No. 2                    | 4                    | 41½                    | 35.60                          | 10.80                                |
| Hensman and Son                       | 4                    | 33                     | 29.00                          | 18.75                                |
| Hornaby and Sons                      | 6                    | 49                     | 35.23                          | 6.79                                 |
| Butlin                                | 4½                   | 50                     | 42.00                          | 14.71                                |
| Garrett and Son*                      | 5                    | 42                     | 26.50                          | 11.65                                |
| Coburn                                | 9                    | 44                     | 52.00                          | 12.48                                |
| Clayton, Shuttleworth, and Co., No. 1 | 6                    | 52                     | 35.40                          | 8.63                                 |
| Ditto ditto, No. 2                    | 6                    | 42                     | Withdrawn.                     |                                      |
| Barrett, Exall, and Andrews           | 4½                   | 26                     | 25.56                          | 9.20                                 |
| Burrell                               | 6                    | 28                     | 35.00                          | 13.10                                |
| Ransomes and May                      | 5                    | 70                     | Withdrawn.                     |                                      |
| Hoe and Hanson                        | 4                    | 83                     | 75.20                          | 25.80                                |

\* Garrett and Son's slide was wrong in this trial, but in a second experiment, tried with Newcastle coal, this engine worked out what would equal

8.63

the comparative time of performing the same amount of work. This, it should be mentioned, is not the observed time, but the time calculated from the registered revolutions of the engine. The pressure of steam and the number of revolutions per minute which were equivalent to the horse-power applied to each machine having been ascertained, the whole number of revolutions made during the trial, divided by the calculated number per minute, gave the number of minutes required for the performance of the work at the specified power and speed of drum. The figures in col. 6 represent the horse-power that would have been required in each case to do the work in one minute; and show therefore, at a glance, the performances of the several machines in respect of speed and power combined. The lowest figures represent the most satisfactory results. Col. 7 shows the quality of the work done in respect of the three points of "clean threshing," "broken grain," and "state of straw." In each case a number is assumed to represent perfect work, which is considered to bear a proper proportion to the importance of the point—so that the total number obtained by each machine, as shown in the last column, may fairly represent the comparative goodness of the work.

The second trial was conducted in precisely the same manner as the first, the only change being that barley was

threshed instead of wheat. Those machines only were allowed to compete which had acquitted themselves satisfactorily at the first trial.

For the guidance of those who are not in the habit of examining tabular statements, it may be useful to point out that the two columns to which attention should be particularly directed are those numbered 6 and 7—the latter being the most important. On ascertaining by the "total" number in col. 7 that a machine has done its work well, col. 6 should next be consulted to ascertain whether under that head it received a high or low figure; if the former, it must be either slow in its performance or heavy in its draught; but, if the latter, it may be inferred that it had threshed wheat well, and the second trial would be referred to to ascertain its capabilities with respect to barley. An examination of this kind will show that the machines which stand first in order of merit are those of Messrs. Holmes, Hensman, and Garrett; and their performances having been in all respects satisfactory, Medals were awarded to each of them.

The shaker attached to Messrs. Holmes's machine was especially commended as being very efficient, and yet adding little to the draught of the machine.

H. S. THOMSON.

#### FIRST TRIAL—WHEAT.

|                     | 1                    | 2                                      | 3   | 4                             | 5   | 6  | 7                              |                                |                               |        |

| 2. Blythe --        | 4                    | 4                                      | 407   | 15.50                         | 2 41½   | 11.76  | 10                             | 12                             | 7                             | 29     |
| 3. Garrett --       | 6                    | 6                                      | 260   | 32.00                         | 2 21  | 13.96  | 18                             | 12                             | 8                             | 38     |
| 4. Crosskill --     | 4                    | 4                                      | 303   | 19.00                         | 2 27  | 9.84   | 16                             | 12                             | 8                             | 36     |
| 5. Hensman --       | 4                    | 4                                      | 358   | 17.50                         | 2 40  | 10.67  | 20                             | 12                             | 8                             | 40     |
| 6. Caborn --        | 6                    | 6                                      | 417   | 26.00                         | 3 5   | 18.48  | 20                             | 8                              | 4                             | 32     |
| 7. Barrett & Co. -- | 6                    | 6                                      | 336   | 26.00                         | 2 58  | 17.88  | 16                             | 10                             | 8                             | 34     |
| 8. Ransomes --      | 4                    | 6                                      | 368   | 26.00                         | 2 41  | 16.44  | 18                             | 6                              | 6                             | 30     |
| 9. Holmes --        | 6                    | 6                                      | 248   | 28.50                         | 2 0   | 12.06  | 20                             | 12                             | 7                             | 39     |
| 10. Smith --        | 3                    | 6                                      | 595   | 24.00                         | 4 0   | 24.00  | 20                             | 11                             | 7                             | 38     |

#### SECOND TRIAL—BARLEY.

|                 |    |    |     |       |      |       |    |    |   |    |
|-----------------|----|----|-----|-------|------|-------|----|----|---|----|
| 1. Garrett --   | -- | -- | 160 | 32.00 | 1 27 | 8.72  | 20 | 10 | 8 | 38 |
| 2. Crosskill -- | -- | -- | 346 | 19.00 | 2 47 | 11.16 | 20 | 11 | 8 | 39 |
| 3. Holmes --    | -- | -- | 168 | 28.50 | 1 20 | 8.19  | 20 | 13 | 8 | 40 |
| 4. Hensman --   | -- | -- | 195 | 17.50 | 1 27 | 6.62  | 15 | 12 | 8 | 35 |

The difference, as shown by the Table, in the power required by different threshing-machines for threshing a given quantity of straw, which was 1 to 3 at Exeter, is not much less now, being still as high as 1 to 2½. The speed, however, with which the straw is passed through the machine must not, of course be made the sole test of excellence. Clean threshing is a most material point, in which some machines are very deficient, as is proved after rain by the grassy verdure of a straw-heap so threshed. Thus the easiest-working machine, Mr. Crosskill's, seems to have gained that ease at the expense of its efficiency, as appears in the column which registers the cleanness of the threshing. On the other hand, clean threshing may be obtained by beating the sheaves too roughly; as must be the case with Mr. Hornsby's, which bruises the straw, and what is worse, breaks the grain. Still, the power required by the three prize machines averages only about 12, while the maximum of power required is just double, namely 24, by Mr. Smith's, which, therefore, of course wastes half the power, whether of horses or steam, that may be applied to it.

A separate trial it will be seen, was made with barley.

Long as the threshing-machine has been known, the maltsters in most counties refuse to buy barley unless threshed by the flail, because most machines bruise the grain, and destroy its power to germinate. The assertion that malt-ing barley could be threshed by machine, would in many parts of England simply be disbelieved. Yet where the best machines are used, the maltsters no longer object to barley so threshed; so that it is most important to test all threshing-machines with barley. Enough, however, has been now demonstrated to convince farmers that they should no longer buy blindly the threshing-machine which comes nearest to hand, buying thereby double or perhaps treble labour for the same or worse work, and leaving their barley, which is, probably, half their crop, to the tedious work of the flail, though the labourers themselves begin to regard that work as too irksome.

There remains only in this class of machinery to apply the test of economy, and compare the cost of threshing by flail, by horse, and by steam. In the two former cases the rick must first be removed into the barn by eight men, a boy, and two horses—I take the numbers as they have been employed on my own farm, because it is difficult to

ascertain such figures, and the comparison will at least be a fair one—

|                   |      |
|-------------------|------|
| 5 men, at 1s. 4d. | 10 8 |
| 1 boy             | 0 10 |
| 2 horses          | 2 0  |

Cost of burning - - - 17 6

The price of threshing wheat by fall varies, with the yield and the district, from 2s. 6d. to 4s. a quarter. Three shillings then will not be an unfair average. If the rick hold forty quarters, we must add 8d. for burning, and the cost will be 3s. 5d. per quarter.

In threshing with the unimproved machines, I find on inquiry that neither my neighbours nor myself have hitherto got out more on an average than thirteen quarters a-day. The supposed rick would take, therefore, three days to thresh:—

|                   |        |
|-------------------|--------|
| 5 men, at 1s. 4d. | £0 6 8 |
| 4 women, at 8d.   | 0 2 8  |
| 1 boy             | 0 0 6  |
| 4 horses, at 3s.  | 0 12 0 |
|                   | 1 2 0  |
|                   | 3      |

|                   |        |
|-------------------|--------|
| 3 days' threshing | 3 6 0  |
| Burning           | 0 17 6 |

£4 3 6

The whole system of horse-machines has cost us, therefore, 2s. a quarter. But improvement has been carried further: for steam-threshing we require additional hands, sixteen instead of ten, but we get over three times the work, passing the rick in one day, not three, through the machine. The figures on steam-threshing will be then as follows:—

|                          |        |
|--------------------------|--------|
| 1 engineer (head carter) | £0 2 6 |
| 10 men, at 1s. 4d.       | 0 13 4 |
| 5 women, at 8d.          | 0 3 4  |
| Coals, 3½ cwt.           | 0 3 6  |

£1 2 8

If we make up this sum to 30s. for the use of the engine, the cost of steam-threshing will be 9d.; the saving as compared with hand-threshing, 2s. 8d., or with horse-threshing 1s. 3d.; an average of 2s. per quarter of wheat—a large saving certainly to be effected in one only of five main departments, but not larger, I believe, than may be shown to arise from the use of improved machinery in most, if not all, of the four other departments as well. It may be objected that credit is given for the value of the horses' labour; and though in valuations horse-work is often charged high, we are apt, I know, as farmers, to regard each particular use of horses as costing us nothing. This view may be even correct on small matters occurring at leisure seasons, but it would be false if applied to a demand like the present, large in itself, distressing also for the horses, and liable to occur at all times of the year. It can have no truth in it at all, when we endeavour, and by reformed implements in all other departments are enabled, to reduce the permanent staff of horses kept on the farms for this plain reason, that, if we do not carry the reduction throughout, we either press the horses unduly at one time, or require horses to be kept which are useless at other seasons.

Since the trial for the Commission, a fresh trial has been made at Bridlington. There the prize was awarded to a machine by Messrs. Clayton, Shuttleworth and Co., which not only threshes out 50 quarters in a day's work, but dresses the corn also to a great extent at the same time; yet requires, as the makers state, only fourteen hands for both purposes; not more hands, therefore, than we have employed to get out with our horse-machines, and afterwards dress 15 quarters:—

|                           |     |
|---------------------------|-----|
| Engineer                  | 2 6 |
| Boiler                    | 2 6 |
| Six men, at 1s. 4d.       | 8 0 |
| Six women or boys, at 8d. | 4 0 |
| Coals, 5 cwt.             | 5 0 |

£12 3 0

If we add 7s. for wear and tear,\* we find the wheat to be threshed and winnowed for the almost incredibly low sum of 7d. only per quarter. Messrs. Clayton, therefore, have now taken the lead in the improvement of threshing-machines.

### 3. Winnowing-machines.

Even winnowing is become a refined process; for instead of trusting the corn to the wind, it is now placed in a machine so discriminating that the best of these, Messrs. HORNSBY'S, required, on the part of the Judges at the York meeting, specific terms for describing its work more than are easy to understand; but the Judges' account is for that very reason worth quoting:—"Several machines," they say, "were tried, but could not get through the grain, shorts, straws, and chaff, as it came from the threshing-machines, without being choked or requiring much more time than Hornsby's, which did its work well, parting the whole into best corn, good tail, tail, whites, screenings, and chaff, at the rate of about fifteen quarters an hour, and dressing over the second time at the rate of above twenty quarters per hour, parting the whole into six parts, as before, in a workmanlike manner." Such masterly mastication and digestion, making the contents of our supposed wheat-rick, forty quarters, in five hours ready for market, must be appreciated by farmers; and Mr. Hornsby's winnower has not lost character at Kensington, as appears by the Judges' Report:—

*Winnowing-machines.*—Messrs. Hornsby and Son are, above all others, the most successful in these machines, dressing more than double as much corn as any other in a rough state. Theirs is fitted with a spike roller, working through a grating, and forms a sort of hopper, separating the corn from the chaff in the rough pulpy state, as it comes from the threshing-machine, without being previously riddled; and can be adjusted to suit corn either in rough chaff or in any other state; the second time over, a slide-board is adjusted in the front of the grating, and is excellent for finishing the corn for market. We therefore awarded it a Medal. Price 132. 10s.

Mr. Gooch exhibited a machine which did its work well, but too slow.

C. B. CHALLONER.

The corn being now fit for the miller, the task of a reporter on agricultural implements fifty years since would have ended; nor is it within this branch to enter on the new process of grinding, by which the finest flour is produced from ordinary red wheat; but though the preparation of food for man belongs to another department, there is an entirely new class of implements belonging to this Jury which must not be passed over.

### V. MACHINES FOR PREPARING THE FOOD OF STOCK.

Formerly our farm stock was fed with hay, or turned out to pick over straw, sometimes with whole turnips thrown to them. But practice, anticipating Baron Liebig's brilliant discoveries in animal physiology, found that the labour of the jaws wasted the beast's muscle and thus retarded his progress. Our stock, therefore, are saved even from that exertion, and distinct machines have been invented for mincing each description of food with which the animals are made ready for market. The most common of these is

#### 1. The Turnip-cutter.

The test of labour saved cannot, of course, be applied where the labour is applied to a new object. These machines, however, have recommended themselves so widely, that to prove their advantages is almost idle. Still it deserves mention that, in the opinion of good farmers, lambs fed with the aid of a turnip-cutter would be worth more at the end of a winter by 8s. a-head than lambs fed on whole turnips, the cost of using the machine being but 1s. per head, and of the machine itself 5l. only. If this be true—and it has not been disputed—this simple instrument gives a saving of 70s. an acre upon the turnip crop. Hitherto the Banbury turnip-cutter has stood almost alone,

\* I am told that this would be a fair allowance for wear and tear on a farm of 500 acres, where the steam-engine is used for chaff-cutting, grinding, &c., as well as threshing.

thousands, I believe, being sold in the year; but in the Exhibition Building it has at last found a rival.

**Turnip-cutters.**—Three of these implements were tried; that of Messrs. Burgess and Key is upon a different principle to those generally in use; their implement cuts a very large amount of roots for sheep and beasts at the same time, exceedingly well, and requires a very small amount of power. There is a great facility of changing any of the knives that may become blunt or broken; and there is a very simple and ingenious method of letting stones or gravel escape before coming in contact with the knives. Price 5*l*. Both for novelty and usefulness we awarded it a Prize Medal.

Mr. B. Samuelson (successor to the late James Gardener, of Banbury) has very much improved that well-known implement. The framework is made of cast-iron, light, portable, and durable, and well adapted for field work. He has also made a great improvement in the facility of getting at, repairing, or adjusting the knives. Price 5*l*. We awarded a Prize Medal.

Mr. Phillips's turnip-cutter was tried, but could not compete either in construction or work with the other two.

C. B. CHALLONER.

## 2. Chaff-cutters.

These instruments, which cut straw into very short lengths for feeding stock, are so called because there not being enough natural chaff for the purpose, artificial chaff was made in this way. At first the straw was cut in a rude box, with a chopper raised by the hand, and cost 2*d*. per basket; then with a circular movement, costing 1*d*.; and may now be cut by steam-power at not much more than  $\frac{1}{4}$ *d*. per basket. The process makes, too, an arable farmer independent of natural meadow; for sheep, it is well known, especially breeding ewes, require much dry food; but this artificial chaff mixed with rape-cake, takes the place for them of hay, or hay may be cut with the straw. It is also worth while to cut hay, though consumed by itself. Even in the new circular chaff-cutters we find a difference as to the labour required by them for preparing a given amount of chaff. The difference, indeed, was so great in the trials at York, that it is worth while to quote some of the figures:—

|           | Price.   | Weight of Chaff cut. | Power required. |                                    |
|-----------|----------|----------------------|-----------------|------------------------------------|
|           | £. s. d. | lbs.                 | lbs.            |                                    |
| Cornes -  | 14 0 0   | 112                  | 14,126          | Did its work well.                 |
| Garrett - | 10 10 0  | 112                  | 31,291          |                                    |
| Crosskill | 18 0 0   | 112                  | 41,800          | This machine made very rough work. |

This table is most instructive; for we find here three first-rate makers staking their reputation in a public trial on their respective instruments, one of which nevertheless requires three men to do badly what another enables one man to do well. Surely farmers must learn from such results a more careful choice of their implements. It is due to the two makers last named to mention that the lesson was not thrown away on them.

**Chaff-cutters.**—Mr. Cornes, of Burbridge, has, in the trials at Kensington, maintained his previous reputation for the greatest economy of power in proportion to the work performed; also the machines of Messrs. Garrett and Son, and Messrs. Smith and Co., of Stamford (17*l*.), are worthy of the highest commendation, the latter for an ingenious application of a spring lever to throw the rollers out of gear when starting the machine. To these three we have therefore awarded a Medal.

C. B. CHALLONER.

## 3. Linseed and Corn Crushers.

The same extraordinary disparity of power required was found also two years since, at the Norwich Meeting, in this class of implements:—

|                | Linseed Crushed. | Power required. |
|----------------|------------------|-----------------|
|                | lbs.             | lbs.            |
| Stanley - - -  | 112              | 24,238          |
| W. Nicholson - | 112              | 94,080          |

In fact this is the greatest difference we have found yet in any machine worked by hand, being about four to

one: so that to obtain the same work four men must turn one machine, while a single labourer turns the other.

**Linseed and Corn Crushers.**—Mr. Stanley, of Peterborough, at present stands unrivalled with this machine. By his recent improvement of a lever in front to relieve the pressure when the corn is first let in upon the rollers, he has perfected this machine, which was much needed, as machines on this principle have been made by various other makers, but have always been subjected to the inconvenience of being choked with the corn at starting. On these trials Mr. Stanley's machine required less power to drive it than others; and was, in consequence, awarded a Prize Medal.

Messrs. Barrett and Exall's crusher merits commendation. Messrs. Garrett and Son have introduced some additional motions, and have thereby added considerably to the friction of their machines.

C. B. CHALLONER.

## 4. Oil-cake Bruisers.

Not being able to procure the thick cake, the machines were tried with the small 3-lb. cakes.

Mr. Nicholson, of Newark-on-Trent, exhibited a machine, the price of which was 5*l*., which did its work very well. Messrs. Hornsby brought two very excellent machines (I think the larger one is to be preferred), breaking for beasts, sheep, and manure equally well. To each of these exhibitors a Prize Medal has been awarded. Others, on the same principle, were tried, but did not do their work so well.

C. B. CHALLONER.

## 5. Mills for grinding fine Meal.

**Mills for grinding fine Meal.**—The best metal mills that have been produced for the operation are those of Messrs. Hurwood, of Ipswich, and Messrs. Crosskill, of Beverley; that of Messrs. Hurwood, which is composed of a series of cutting rings screwed upon a cast-iron plate, having the dress somewhat resembling the common millstone; the drift increased from the centre, to enable it to clear itself. The rings appear to be easily replaced by new ones when worn out, which is a great advantage over the old mills. This mill did six bushels of barley per hour, with a power of a little more than three horses, and is applicable to beans, barley, and oats. We awarded it a Prize Medal.

Messrs. Crosskill's is an American invention, consisting of a number of cast-iron plates turned upon a circular groove, either fine or coarse, dependent upon the work required, and fixed eccentric, which gives them a sort of clip. The mill requires great power, and should be driven at great speed. By changing the plates it will grind anything from linseed to flint-stones. In the trials at Kensington it ground linseed, barley, beans, and oats very well. Price 28*l*. We awarded it a Prize Medal.

Mr. Bentall, of Woodbridge, exhibited a small steel mill, requiring very little power, which split beans very well, at the rate of ten pecks per hour, and deserves commendation. Price 6*l*. 6*s*.

C. B. CHALLONER.

## 6. Gorse Bruisers.

These implements have reached a high degree of perfection, but whether their application has increased in proportion, or has been found profitable, there is no sufficient information at hand.

Mr. Burrell's, of Thetford, did the most and the best work; and although it consumed rather more power than some others in bruising the gorse, it did oats and linseed at a moderate amount of power. We therefore awarded it a Prize Medal. Price 27*l*.

Messrs. Barrett and Exall, of Reading, exhibited a machine worthy of commendation. Price 25*l*.

Messrs. White, of Holborn, exhibited a machine that reduced the gorse into the most pulpy state, but required a great increase of power. The price (60*l*.) is beyond the reach of a farmer, which, I am told, they propose to reduce; but that was the price officially announced at the time of the trials.

C. B. CHALLONER.

## 7. Steaming Apparatus.

Besides the various modes of subdividing, it has been often proposed to cook the food of animals; but the practice has not spread widely, and the advantage must be regarded as doubtful, excepting as regards the steaming

of potatoes for pigs; but even diseased potatoes, if not too far gone, by being thus treated, may be rendered good victuals and be stored up for months. It seems hardly worth while to set up expensive fixtures for this purpose only, especially as we have an excellent apparatus, Mr. STANLEY'S, which, like Soyer's magic stove, may be used when and where it is wanted. When tried\* at York, it heated 126 gallons of water, while another\* heated but 70, little more than half, with the same allowance of fuel; yet this inferior one had been the best two years before.

#### VII. CHURNS.

The pace of the churn was first accelerated by the Americans, who sent us over a churn within the last few years that produced butter after ten minutes' work. It is not quite clear, however, whether this speed be compatible with the finest quality, for the New York Agricul-

tural Society was not satisfied with the butter so rapidly made. The time in the present trials was reduced to two minutes, and even to one minute, but in the latter case with cream which, having come from Jersey, had been already half churned by the steam-packer.

Thirteen churns were tried in the first trial, with ordinary cream of good quality; the annexed tabular form will give the results. As will be seen, many of the churns worked equally well, and some of them which did not do so well would perhaps have shown a different result in an atmosphere more congenial to the making of butter. However, in both trials, the small family churn of Lavoisy did its work so well that we awarded it a Prize Medal. Those of Wilkinson, and Burgess and Key, also proved themselves to be excellent churns; and there was awarded to each a Prize Medal. The Belgian churn of Duclêne, though not quite perfect in every part, we consider entitled, as among the foreign churns, to a Prize Medal.

FIRST TRIAL OF CHURNS.

| Exhibitors.         | Cream.  |           | Time.    |     | Butter.       |              | Residus. | Quality. |     | Form of Churn. |     | Thermometer. |        |
|---------------------|---------|-----------|----------|-----|---------------|--------------|----------|----------|-----|----------------|-----|--------------|--------|
|                     | Quarts. | Min. sec. | lbs. oz. |     |               |              |          |          |     |                |     | Air.         | Cream. |
| Wilkinson - - - -   | 4       | 11 0      | 3 8      | - - | Best - - -    | Wood.        | - -      | - -      | - - | Wood.          | - - | 70           | 69     |

#### VII. DRAINING.

This last class of machines, those connected with draining, ought perhaps to have formed the first class, inasmuch as draining is the only road to good culture on land which lies wet; but as much land does not require draining, and as it does not belong to the regular task of the farmer, but is a work to be done once for all by the landlord, the machines employed in this mode of improvement have been reserved to the end.

##### 1. Tile Machines.

Twelve years ago draining-tiles were made by hand, cumbersome arches with flat soles, costing respectively 50s. and 25s. per 1,000. Pipes have been substituted for these, made by machinery, which squeezes out clay from a box through circular holes, exactly as macaroni is made at Naples, and the cost of these pipes averages from 20s. down to 12s. per 1,000. The old price was almost prohibitory of permanent drainage, excepting where stones were at hand; the new invention has reduced this permanent improvement to a rate of 4l. or 3l. per acre, not exceeding in cost the manure given to a single turnip crop in some high-farmed districts. This result has been obtained by a most spirited competition among mechanics, as no less than thirty-four different tile machines competed in 1848 at the York Meeting. Since then the struggle has been practically between three only, on

which, in the present year, we have the following report:—

*Trial of Tile Machinery.*—I recommend to the consideration of the Jury the Tile and Brick Machines of Mr. Clayton, Mr. Scragg, and Mr. Whitehead.

I first tested their capacity in screening the earth. The result of this trial was that in five minutes

Mr. Clayton screened - 327 lbs. 2 men and boy.

Mr. Whitehead - - - 361 " 2 men.

Mr. Scragg - - - - 202 " 2 "

I give the preference to Mr. Clayton's screen, as it clears itself, and the portion rejected consisted almost entirely of small stones, &c.; whereas the screens of Mr. Whitehead and Mr. Scragg retained a large portion of clay.

In the manufacture of large pipes, nine inches in diameter, by horizontal delivery and the use of a cylindrical horse, the machine of Mr. Whitehead was perfect.

Mr. Scragg has much simplified the internal arrangement of his machine by substituting a chain for the rack and pinion: the pipes from this machine were not to be surpassed for regularity and uniformity of shape. After a careful examination of the working of these machines, we recommend the horizontal delivery of Mr. Scragg and Mr. Whitehead in preference to the vertical delivery of Mr. Clayton, but especially call your attention to Roberts's patent hollow and bonding bricks, as made by Clayton's machine.

A. HAMOND.

\* The trial of Mr. Stanley's apparatus was overlooked accidentally, because a trial was thought unnecessary, there being no moveable apparatus in competition; but the Jury having decided that no prize should be awarded without trial, the oversight could not be remedied. There was also a fixed apparatus which could not have been tried.

The pipes so made are placed under ground with narrow spades; but in the form of the narrowest spade, if I may venture to speak from my own experience, it is clear that, so far as regards clay subsoils, a step has been taken backward in substituting a concave tool for the old triangular lance-headed tool of Essex, with which far more

work can be done, by less exertion, too, on the part of the labourer. There is hope, however, that on clay soils manual toil will be superseded by the use of

## 2. The Draining Plough.

But for the American Reapers, Mr. FOWLER's draining plough\* would have formed the most remarkable feature in the agricultural department of the Exhibition. Wonderful as it is to see the standing wheat shorn levelly low by a pair of horses walking along its edge, it is hardly, if at all, less wonderful, nor did it excite less interest or surprise among the crowd of spectators when the trial was made at this place, to see two horses at work by the side of a field on a capstan which, by an invisible wire-rope, draws towards itself a low framework, leaving but the trace of a narrow slit on the surface. If you pass, however, to the other side of the field, which the framework has quitted, you perceive that it has been dragging after it a string of pipes, which still following the plough's snout, that burrows all the while four feet below ground, twists itself like a gigantic red-worm into the earth, so that in a few minutes, when the framework has reached the capstan, the string is withdrawn from the necklace, and you are assured that a drain has thus been invisibly formed under your feet. The Jury decided as follows:—

The implement went through the trial very well, laying in the tiles with great apparent ease, worked by two horses, with a capstan which was firmly and easily fixed into the ground, and afforded a firm traction to the plough by means of a wire rope and pulley. Progress has been made, since the implement was exhibited at Exeter, in rendering the level of the drains in a degree independent of the level of the surface; but there is still room for further improvement in giving to the drain a *uniform* incline.

The award, therefore, of the Jury was Honourable Mention. Since that trial I have thought it right to make further inquiry into the work of the draining plough. In the first place, the trial drains were opened and laid bare from end to end. Straightness is of course one requisite, and the pipes were laid straight; closeness of contact another, and they were perfectly joined. In level, the point on which the Jury doubted the perfection of the work, there was some deficiency, which, on entirely flat ground such as this, was a decided fault. That fault, however, has since been remedied for clay land at least. As the plough was shown last year at Exeter, it could not possibly lay a level drain, because, its under and upper parts being fixed at any unvarying distance, any unevenness of undulatory surface must be faithfully copied by an undulating drain below. This year the two parts were so connected that the workman, by turning a screw, can raise or lower the underground snout which burrows out the drain. But at the trial the use of this screw depended on the workman's judgment, which cannot give the drain absolute accuracy. A balanced level, however, has now been added to the plough, by which the changes of surface are made plain to his eye. Other improvements have also been made in the implement. The horse-power required has been reduced by a fourth, and the windlass at which the horses work need now be shifted only once in the day. As to the economy of using the draining plough, it is too expensive to purchase, unless for a large landowner, but it may be hired by the year or the month. Its inventor is also ready to execute work at his own risk by contract, at a saving of from one-third to two-thirds on hand labour—the greater the depth, the greater being the saving. I have only seen the actual cost of two drainages that have been made by this plough. They were were both without tiles and shallow, being only 2½ feet deep. Taking the highest of them, and adding the cost of tiles, the price of tile-draining land at that depth, and at 33 feet apart, would be 14s. only for work, and with 1½-inch pipes, at 10s. per 1,000, 18s. 9d. for tiles, all together 17. 3s. 9d., including horses and hire of machine. The plough goes as well, however, at a depth of 4 feet,

nor could the additional cost be material. The plough has worked on the following farms:—

|  | Acres.      | Depth.<br>ft. in.     |
|--|-------------|-----------------------|
| Mr. Fowler, Melksham . . .                           | 14          | 2 6 with pipes.       |
| Mr. Newman, ditto . . .                              | 10          | 2 0 ditto.            |
| Mr. Blandford, near ditto . .                        | 30          | 3 6 ditto.            |
| Mr. Purch, Down Ampney . .                           | 100         | without pipes.        |
| Mr. Hall, Brentwood . . .                            | 200         | 2 6 with and without. |
| Wormwood Scrubbs 40 from 2 ft. to 4 ft., with tiles. |             |                       |
| Mr. Harris, Darlington . . .                         | now working | 3 6                   |

In clay subsoils, with a gentle fall, the success of this new implement seems to be beyond doubt, and in all circumstances the inventor is ready to undertake the risk of the execution.

In now closing this Report, I shall be permitted to say that, although it is impossible adequately to value any productive machinery without detailing its objects and estimating its power to diminish human toil, or to increase the results of that toil, I could not have ventured to enter so far into the practice of husbandry, but for the interest your Royal Highness has long taken in these pursuits, and, above all, from the high concern entertained by you in the welfare of that important class among Her Majesty's subjects to whom agriculture affords the means not of harmless or useful amusement merely, but of anxious subsistence, not unaccompanied now with serious misgiving. A sure conviction, founded on no short experience, that those new implements which in the great Exhibition afforded not the least conspicuous testimony to the advance of English skill in devising mechanical means for the abridgment of labour, can practically afford to the English farmer, if rightly understood, important, easy, and immediate assistance, has emboldened me to pursue the necessary chain of evidence with, I fear, tedious minuteness; but that minuteness will, I trust, be excused, if it shall have established any definite truths, which, as affecting the prosperity of so important a body of men, may be thought in some degree to claim even national importance; and, the claim alone will, I well know, have secured your Royal Highness's indulgent attention.

It seems proved, then, that within the last twelve years, since annual country shows of implements were established by Lord Spencer, Mr. Handley, and others yet living, old implements have been improved, and new ones devised, whose performances stand the necessary inquiry as to the amount of saving they can effect. To ascertain that amount precisely is difficult; but looking through the successive stages of management, and seeing that the owner of a stock farm is enabled in the preparation of his land, by using lighter ploughs, to cast off one horse in three, and by adopting other simple tools to dispense altogether with a great part of his ploughing—that in the culture of crops by the various drills, horse-labour can be partly reduced, the seed otherwise wanted partly saved, and the use of manures greatly economised, while the horse-hoe replaces the hoe at one-half the expense—that at harvest the American Reaper can effect nearly thirty men's work, while the Scotch cart replaces the old English waggon with exactly half the number of horses—that in preparing corn for man's food the steam threshing-machine saves two-thirds of our former expense—and in preparing food for stock, the turnip-cutter, at an outlay of 1s., adds 8s. a-head in one winter to the value of sheep—lastly, that, in the indispensable but costly operation of draining, the materials have been reduced from 80s. to 15s.—to one-fifth, namely, of their former cost; it seems to be proved that the efforts of agricultural mechanists have been so far successful, as in all these main branches of farming labour, taken together, to effect a saving on outgoings, or else an increase of incomes, of not less than one-half.\*

\* As mere reasoning seldom carries conviction, I may be permitted to mention that whereas in estimates by excellent farmers 12 horses are still assumed to be necessary for a farm of 400 acres, though with improved farming, I find now that I can work 460 acres of a mixed farm with 8 horses, which are by no means confined to the work of the farm.—P. H. P.

\* The machinery is made by Messrs. Fowler and Fry, Templegate, Bristol.

This saving of labour or expense, though large for land—a material certainly very intractable—is small as compared with the saving effected in the weaving of calico, or the knitting of stockings. But it is important to observe, on the other hand, that the cost of the means which produce the saving is comparatively insignificant. When the distaff and knitting-needle were abolished, huge factories had to be built, and filled with intricate clockwork of spinning-jennies and looms, costing thousands of pounds. In agriculture we buy a few simple durable tools; and it is evident that a farmer setting up now in business, who, instead of the old waggons with three horses each, should buy one-horse carts, and the smaller number of horses required by such carts and by other improved machinery, would find that, without any increase of outlay whatever beyond the old scale, he could acquire all requisite modern machinery, with one exception, indeed—the steam-engine, but the steam-engine is often hired. It is therefore further demonstrated that *the new agricultural machines have, with reference to the amount of saving produced by them, the merit of very great cheapness.*

There is a further effect of machinery upon agriculture which has hitherto been overlooked. The main difficulty of farming has always lain in its uncertainty. Though machinery has not altogether cured, it certainly has much mitigated, this evil. On undrained clays a wet winter may destroy half the yield of the wheat. On the same land drained, the wheat may escape altogether unhurt, and you may also plough heavy land in wet weather when drained, though you could not before. Upon any land wheat may suffer in winter, but in spring the presser settles it in its bed, and the manure distributor with a cheap sprinkling restores it to vigour. In sowing barley earliness may save the crop; but the ground is often too cloddy, though the season is wearing away, and May-drought approaching. This cloddiness may be prevented, as has been said, by the paring-plough, or, if it could not be prevented, may be remedied by the clod-crusher or Norwegian harrow; and besides these implements, the cultivator does the plough's work in one-fourth of the former time, thus enabling the farmer to profit by the auspicious hour of seed-time. And so too with the turnip: the land, being prepared for it in the previous autumn and winter, is moist to receive the seed; the dry drill, supplying it with superphosphate, saves it almost certainly from the fly; or yet more, the water-drill, anticipating the clouds, makes its seed-time independent of weather while the horse-hoe afterwards preserves it from neglect in the busiest harvest-time. Again, while machinery remedies the absence, it also guards against the inconvenient arrival of rain, by making hay and now even reaping corn while the sun shines. It may be further said, then, that *machinery has given to farming what it most wanted, not absolute, indeed, but comparative certainty.*

I wish I could add that the use of machinery has advanced as rapidly as its improvement. Still it has advanced greatly, as is shown by the increase, not only of implements but of eminent implement-makers, and the sale has never been so great as it has been this year. Yet even the best new machines are not yet adopted into general use. This incomplete progress may, however, easily be accounted for. The farmer, whose life is secluded, has little opportunity of seeing them, and it is remarkable that nearly all our first implement-makers live on the east side of England, in those four counties from which the other great improvements of agriculture have also proceeded. For threshing-machines again, though universal, until very lately no record of their work has been published, so that a farmer in one county, threshing thirteen quarters only a day, could not possibly ascertain that in another county three times that amount was the proper work of a day.

But it must be further admitted, that few even of our best farmers, though they may possess the new implements, carry their use thoroughly out. It seems evident that *the new implements require a new system.* As yet many farmers use the drill, and do not use the horse-hoe afterwards, the use of which is pointed out by the drill, while most farmers still use the plough previously, which the drill may have rendered superfluous. It is of course very difficult to give up old practices, but the result of the whole inquiry into agricultural machinery appears to be this,—that, inasmuch as the new machinery effects a great saving of labour, and is also exceedingly inexpensive, giving also moderate certainty to a business proverbial for its precariousness, farmers ought no longer to bind themselves down by ancient customs in husbandry, but should consider at once how these practices may be reformed altogether, in order thoroughly to carry out the advantages of modern mechanics. They should look as much to a shed furnished with suitable implements as to their stables, remembering that the best of these implements, though it cost as much as a horse, may take the place of a horse; and, furthermore, when once purchased, does not, like the horse, entail a weekly expense afterwards. That this extension as well as improvement will come to pass in the mechanics of husbandry there is no reason to doubt, nor that both have been accelerated by the opportunity for careful study of agricultural implements which has been afforded during five months through their exhibition, under your Royal Highness's auspices, among all the other products of human industry.

NOTE.—In this Report it occasionally happens that an Exhibitor is named more than once in connexion with different articles he has brought forward as entitled to a Medal; as, however, no person can obtain more than one Medal in the same Class, that mark of distinction must be understood to represent the excellence of each of the objects rewarded.

## CLASS X.

PHILOSOPHICAL INSTRUMENTS AND PROCESSES DEPENDING UPON  
THEIR USE.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the pages in the  
OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

## Jury.

- Sir DAVID BREWSTER, F.R.S., *Chairman*, St. Andrews, Fifeshire, N.B.; Principal of the University, St. Andrews.  
 Professor COLLADON, Switzerland.  
 E. B. DENISON, 42 Queen Ann Street.  
 J. GLAISHER, F.R.S., *Reporter*, 13 Dartmouth Terrace, Lewisham; Observer in Greenwich Observatory.  
 Sir JOHN HERSCHEL, Bart., F.R.S., 32 Harley Street; Master of the Mint.  
 Professor HERTZ, Denmark.  
 E. R. LESLIE, R.A., United States; Artist.  
 L. MATHIEU, France; Member of Bureau of Longitude, of Institute, and of Central Jury.  
 W. H. MILLER, F.R.S., Searoe Terrace, Cambridge; Professor of Mineralogy.  
 RICHARD PORTER, A.M., University College, London; Professor of Natural Philosophy.  
 Professor SCHUBART, Zollverein; Professor of Chemistry and Natural Philosophy.  
 Baron ARMAND SEGNER, France; Member of Institute, &c.

## Associates.

- J. S. BOWENBANK, 3 Highbury Grove.  
 Rev. W. S. KINGSLEY, Sidney College, Cambridge; Fellow of Sidney College.  
 L. A. J. QUETLET, Belgium; Secretary to the Royal Academy at Brussels (*Juror in Class XXX.*)  
 Lord WROTTSLEY, 31 St. James's Place.

The duties of the Jury upon Philosophical Instruments have been found to be very heavy, as indeed might be expected in a field so vast,—including instruments relating to Astronomy, Optics, Light, Heat, Electricity, Magnetism, Acoustics, Meteorology, &c.; in fact, all relating to Physical Science, collected by a large number of exhibitors.

Astronomical instruments claim our first attention, the exhibitors of these, though few in number, have effected a most beneficial advance by the use of a few parts in their construction as possible; this is mainly observable in the British portion. The workmanship of those exhibited by Germany deserves the highest praise; the instruments are, however, few in number, and do not fully represent German art.

America claims particular notice by the application of electro-magnetism to the registration of astronomical observations, thus enabling the hand to do the work of the mind. This method has the farther advantage of enabling us to record the observations taken at widely separated Observatories, the length of the wire used being immaterial; thus is established a means the best possible for the determination of the difference of longitude. Observatories so connected afford the means of performing the most delicate experiments dependent upon the appreciation of minute portions of time. This method has been recently used in America, for the determination of the wave-time of electrical currents; from which experiments it would seem that its velocity of propagation is much smaller than that determined by Wheatstone.\*

Of nautical instruments, there are several exhibitors; but with the exception of those of America by ERICSSON and ST. JOHN, there is but little novelty of construction. In surveying and levelling instruments, beyond some improvements observable in those exhibited by Austria, there is no novelty. In optics there are many exhibitors, and we

remark the improvement of optical glasses in England, France, and Switzerland, and that the construction of large discs of glass for telescopes, in England, promises to add considerable optical power, and thereby tend to the advancement of Astronomy, &c. Of microscopes the British are by far the best. In physical optics generally, France is pre-eminent, having exhibited a number of delicately-constructed instruments, none of the same kind being contributed by any other nation; she also excels in lenses and in prisms. There are many other classes of optical instruments to be specified hereafter.

There are many photographic cameras, to the improvement of which much attention is at present being paid in both England and France. This leads us to the most remarkable discovery of modern times,—the art of *Photography*,—and never before was so rich a collection of photographic pictures brought together, the products of England, France, Austria, and America.

Before going further, it would be well to inquire into the utility of the photographic process as regards its application to art and science,—and, indirectly, to literature,—by affording a faithful transcript of authentic papers and original documents, upon which subsequent literary and historical research must necessarily be greatly dependent. That photography is yet in its infancy, there can be little doubt; and it is more than probable that its present application, (which we believe to be well represented in the Exhibition,) is no more its ultimatum than were the first applications of the telescope, shortly after the chance placing of two pieces of glass by Jansen's children had led to its invention. Who, at that time, could have predicted the important part that the instrument, based upon that discovery, was destined to play in the world of science? or have foreseen the excellence which it has since attained by successive improvements—even now making,—and of which the Exhibition affords ample proof.

Viewing Photography in connection with Art, it may

\* See Gould's *Astronomical Journal*, vol. 1, Nos. 2, 7, and 14.

at first appear as if a vast and powerful rival had risen up against and was destined to depress her in exact proportion to the superiority of the operations of nature over those of man. In its success, we perhaps expect to behold a transcript of objects and compositions more elaborate and more truthful than any the greatest genius could ever hope to achieve. United to this, and in addition to the rich Vandyke browns and Claude Lorraine tints of many of the works now before us, by the agency of chemicals whose existence is yet unknown, we may see foreshadowed a perfection of colouring as yet never imagined. By improvements in the camera and the daily increasing practical knowledge of experimenters, we may expect to behold compositions, embodying a degree of reality otherwise beyond our power of attainment. The truthful delineation of the various and just relations of the architectural edifice; the groups of figures at its base; the middle distance blended into the horizon by gradations so fine and truthful as to defy the utmost efforts on our part to surpass or even equal; are indications only of that which will ultimately be achieved by the photographer, rich in experience and knowledge of the processes of photographic art.

But this is a superficial and imperfect view of the case, —not as regards the ultimate perfection of photography itself, but as concerning its influence upon art. With art, doubtless, its future destiny will be closely linked; but so far from becoming a rival, it will prove a most useful auxiliary, and a means by which the artist of merit may rise higher in reputation and eminence. By using photography as a means of replacing the purely mechanical parts of his labour, the work of the artist may be much lightened; and as, by speedy transit from place to place, man's life is virtually lengthened, so by relieving his path from that part of his labour which involves an expenditure of time disproportionate to the end attained, one great obstacle to the achievement of success is removed. Never need the artist fear that the employment of its services in conjunction with his pencil, or his adaptation of it in any way to his art, will ever derogate from that art, or render him a servile copyist; we may rather predict that each improvement in photography will tend to place both the painter's and the sculptor's art on a firmer and surer basis. It is likely that time will show that this beautiful compound of art and science will essentially cast its weight into the balance of art, and in future render itself more and more inseparable from, and essential to, her interests.

That Photography will have a great tendency to depress mediocrity, we may safely predict; that, from the date of the general application of Photography to the illustration of scenes daily passing around us, will commence a new era in pictorial representation; that it will greatly enrich us with authentic records of works, that would otherwise pass away without a single detaining effort from the hand of the artist, owing to their being of too transient a nature to admit of the accuracy and detail necessary to give it value in future ages; —is attested by the various and excellent representations which we now possess of the Exhibition building itself, in all its stages, by the faithful and well-executed photographic pictures of MM. Martens, Claudet, &c. Great is its usefulness as applied to transitory scenes of the above kind, and incalculable will be the advantage posterity is sure to reap from the ever increasing collection of such truly graphic representations; and great service, too, will the plain and truthful records of Photography afford to the historian of future ages. As applied to the illustration of works of the present day, it may be of two-fold service. By its application may be superseded the works of individuals, in whose hands illustration is rendered a mere trade, and the directing of whose exertions into another channel would be a means of removing many obstructions which hinder the advance of art. At the same time, the many books we possess for the education of the young, which are crowded with illustrations unfortunately but too well calculated to produce most erroneous impressions, would at once give way before the truthful representations of photography, which, by diffusing a more correct taste, would render essential aid to art herself.

Let us now view Photography in its applications to science. A process by which transient actions are rendered permanent, and which enables nature to do her own work, or in other words, which causes facts permanently to record themselves,—is 'so well fitted for the purposes of science to be long overlooked; but the difficulties to be overcome in its application, have been, and still are great, and the results proportionably few in number; we consider, however, that the commencement of a systematic application of the photographic process to the purposes of astronomy is indicated by the daguerreotype of the moon by Mr. Whipple (451, p. 1464); and great indeed will be the benefit conferred upon astronomical science, when we obtain permanent representations of the celestial bodies and their relative positions, transmitted through the agency of light.\* Another illustration is afforded by the self-registering apparatus of Mr. Brooke (pp. 422-426), in which nature is made to perform the operations of a corps of observers, by an application of what must be considered a few only of the first principles of photography. That its application in causing instruments which are continuous and delicate in their action, to register their own work, must be attended with advantages — is evident to every reflecting mind; and points to some of the further advantages science is likely to derive from the ultimate perfection of the photographic processes.

As applied to the preservation of documentary collections, and thus indirectly to the purposes of literature, its use is too important to be passed over in silence. How often has the historian, in his search after authentic papers, and original documents, found them only to regret that, to posterity he must be the chronicler of events, the vouchers for which will have perished by the unavoidable ravages of time, or, as in too many cases, by supine neglect. To make use of the means afforded by photography to procure fac-similes of these is a duty we owe not only to posterity, but to our forefathers. Again— as applied to valuable documents of the present day, either testamentary or legislative, how important to secure photographic transcripts of these, which, being of indisputable authority, shall be also perfectly unavailable for any purpose other than that intended.

Let us now turn our attention to the collection before us, in which for daguerreotype portraits, America stands prominently forward;—France, first in order of merit for calotypes, or sun-pictures;— England, possessing a distinct character of her own, and presenting illustrations of nearly all the processes which have as yet been adopted. America stands alone for stern development of character; her works, with few exceptions, reject all accessories, present a faithful transcript of the subject, and yield to none in excellence of execution. France, in her daguerreotypes, of which she has but few, offers bright sunny representations; their effect rather injured than improved by too great masses of sunlight; but in her calotypes she stands unrivalled, and all but rejecting the processes of Daguerre, has concentrated all her energies in the further development of those of Talbot and his school.

Eminent amidst the exhibitors of calotypes, is M. MARTENS (610, p. 1207), whose works we may say with certainty, have never been surpassed; their colour, arrangement, and perfect finish, call forth the highest admiration: his success is not confined to one class of delineation in particular, the individual works comprising his collection, being nearly all of equal merit.

On turning to the photography exhibited by the United Kingdom, we find CLAUDET (296, p. 440) leading the way, and adding to the many improvements introduced by him into the various processes of the art by presenting the image *direct* instead of *inverted*: this is the distinguishing feature of his collection, and is the result of patient and untiring research in that class of investigation peculiar to himself.

\* The success of this application of photography must be dependent, to a considerable extent, on the object-glass of the telescope. The Report on Telescopes will show whether the improvements in this department of optics are commensurate with the requirements of photographic representations of this class.

Ross and Thomson, of Edinburgh (299, p. 839), are fairly entitled to attentive consideration from their successful use of the albumenized glass, which they prepare by a process different to that adopted by M. Niepce, its originator, applying the albumen so as to ensure its even distribution, upon which evenness the success of the picture is mainly dependent. The pictures in their collection combine, with exceeding delicacy of execution, a richness of colour equal to that of Martens, but surpass him in the diversity of tints; the collection, besides embracing a long range of sepia tints and Vandyke browns, includes a small picture the colour of which is *blue*, and as this is a hitherto unprecedented result, we are led to give it weight, and will, in another place, describe the process by which it is produced. Some details connected with the methods adopted by Messrs. Ross and Thomson, and kindly furnished by them, are subjoined.

The process for producing negative Talbotypes, on glass, is as follows:—The whites of two eggs, being a quantity sufficient for coating a plate of glass 12 inches square, are placed in a bowl, and cleared from all opaque particles; ten drops of a saturated solution of iodide of potassium are added for each egg, and two-thirds of a wine-glass of water for both,—the whole being then beaten up to a light froth and carefully covered up and left to regain its liquid state. The glass to be coated is well cleaned with a solution of pure water and soda, or potash, and rubbed quite dry with a silk rag. The mixture is then poured on as evenly as possible, and fastening a piece of wire to the opposite corners, the excess of albumen is poured off by turning the plate gently upside down; it is afterwards made to revolve before a clear fire, by a thread of worsted tied to the suspending wire; when the albumen begins to crack, the plate should be removed to a greater distance, and there suffered to remain until equally cracked all over. To render the plate so prepared fit for the camera, it is breathed upon, to give it a degree of softness and to cause it to absorb as much silver as possible; it is then dipped (the prepared side upwards) very gently in a bath of nitrate of silver, prepared in the proportion of 60 or 70 grains to an ounce of water, the plate being prevented from touching the bottom of the vessel by a piece of bent glass, or metal covered with wax. It is then washed in a large dish of clean water, by repeated dippings, care being taken to keep the water running in the same direction. The plate is then placed in the camera, and if the picture when taken, is to be immediately developed, a quantity of acetic acid is added.

The mode of developing the image is as follows:—a quantity of saturated gallic acid is poured on the plate, and spread evenly with soft cotton-wool, after which, when the picture has well appeared, a small quantity of gallic acid is mixed with the nitrate of silver solution, and spread over the glass, which gives the development strength, and renders it more rapid. At this stage of the operation, a solution of hyposulphate of soda (50 grains to an ounce of water) is poured over the picture, and carefully spread with clean cotton; the process is then completed by pouring some water from a jug very gently over the surface.

The negative proof so obtained is transferred to paper by floating the latter on a solution of common salt (5 grains to an ounce of water) for a space of two minutes; it is then pinned up to dry and floated on a solution of nitrate of silver (70 grains to an ounce of water) for three minutes; it is then dried in the dark, and afterwards placed with its prepared side to the prepared side of the glass negative, and screwed in the pressure frame with a plate of glass below to ensure its close contact. The pressure frame should be surrounded with black boards to cut off the rays of light from the sides. To fix the impression, it should be first washed in cold water, then in hyposulphate of soda (100 grains to an ounce of water) for 15 minutes. It is then washed once in cold water, five or six times in boiling water, and finally suffered to remain an entire night in cold water, so as to remove entirely the remaining hyposulphate of soda, which would, in course of time, eat out the picture if allowed to remain.

The photograph thus obtained is afterwards mounted

upon card-board, and pressed on a warm plate of steel, to communicate a slight glaze, which may be considered an improvement to its appearance.

The process we have just detailed is good in many points, but defective chiefly in one—sensitiveness; every effort to increase which has hitherto been attended with a softening of the albumen. This is a difficulty, but one which Messrs. Ross and Thomson will doubtless overcome.

The *positives* on glass are transferred and fixed in the usual manner (the albumen being mixed with salt instead of iodide of potassium), with the addition of pure plaster of Paris, which being mixed with the solution is poured on the face of the picture, and adhering to the albumen in a manner hermetically seals it, and thus effectually preserves it from injury.

This admirable system is, we believe, entirely due to Messrs. Ross and Thomson, whose collection of Talbotypes amply attests the superiority of their method; and indeed, as is the case of Mr. BRUCKLE (301, p. 840), of M. MARTENS, or of any highly-successful photographer, it is but fair to infer that the superiority observable in their productions is due to their improvement of the processes which they have adopted.

Whether the followers of Talbot will ever obtain a pre-eminence over those of Daguerre, or *vice versa*, is a question for time to solve; at present the two systems appear in the British Department of the Exhibition to be equally well represented; the followers of each, with few exceptions, laying claim to some improvement or peculiarity of manipulation. For example, in addition to the cases already mentioned may be included those of MAYALL (pp. 439, 440), who calls attention to his crayon daguerreotype, an invention of his own, and BEARD (p. 440), whose patent enamelled process is one of the very few instances of a patent having been obtained for any improvement connected with this art. Great as is the satisfaction with which we regard the efforts made for perfecting the processes of Daguerre and Talbot, still greater is that with which we observe experimenters divulging the processes they have adopted; the hitherto all but total avoidance of patent enrolment must be considered a distinctive feature of this art, to which fact, doubtless, added to the ready divulging of improvements, is chiefly due the rapidity by which up to the present time its progress has been characterized. The publication of each new process opens a fresh field of philosophical inquiry, gives to man increased physical knowledge, and may work great changes in his moral destinies.

We cannot pass from the subject of photography without alluding to a loss recently experienced in the death of its founder, M. Daguerre, whilst the Jury were engaged in their duties, and we feel it due from us not to let his memory pass unnoticed. In him was lost one of the lights of the age.

We now proceed to Electric Telegraphs, of which a great variety are placed in the Exhibition, many of them are remarkable for novelty of construction, and for important improvements. In the section devoted to their description we shall speak of them at some length.

When Oerter, in 1820, linked together the sciences of electricity and magnetism, great hopes were entertained of the application of electro-magnetism to the movement of machines: and as in the Exhibition there are several arrangements for obtaining motive power in this way, we are far from despairing of its successful application to mechanical motion.\*

When Faraday obtained the converse of electro-magnetism, by induced electricity from magnets in motion, he originated magneto-electricity, and it is possible that its successful application to the purposes of the electric telegraph will supersede the use of galvanic electricity; the experiments which were made before us with the magneto-electric telegraph were satisfactory.

The application of voltaic action, by coating the inferior metals with the superior, is shown in the Exhibition in some beautiful electrolyses and intaglios; also in a recent

\* See Jacobi's papers in Taylor's Scientific Memoirs; and also Lens on Electro-magnetism in the same work.

and highly important application by T. H. Henry, Esq., F.R.S., as shown in the coating beams of balances with platinum and palladium.

Chemistry and chemical apparatus need not detain us long—the Exhibition presenting little (in Class X.) that is new, excepting the application of the former to the extinguishing of fire by Mr. Phillips (Class V., 92, p. 222), who has successfully brought this element under our immediate control by the agency of carbonic-acid gas, nitrogen, and aqueous vapour. His contrivance, by which these agents are evolved, differs materially in its action from that of water, which simply cools the burning substance to a temperature too low for the existence of inflammable gas, but does not at all interfere with the current of fresh air, every accession of which is attended with a fresh increase of combustion. The chemical agents constituting the gaseous vapour generated by this machine, on the contrary, are highly inimical to fire, chiefly from the fact of their entirely preventing all access of pure air to the burning mass. There is another patented application of this kind, but we are ignorant of its details and application.

The Planimeters exhibited claim some attention, there being several ingenious machines of this kind adapted to the determination of areas of plane surfaces by mechanical means.

There are several exhibitors of air-pumps, who have exercised much ingenuity.

There are various machines for standard measures of length exhibited, two of which are extremely beautiful.

Calculating Machines claim some attention as a mechanical power by which the hand is made to do the work of the mind; and operose and long calculations, requiring much strained attention, are performed by turning a handle. Two such machines are shown, which performed well and accurately.

We cannot help recording how clearly the injurious effects of patent enrolments on science were shown in the course of our labours; many of the ingenious contrivances exhibited proved to be merely variations, for the avoidance of the infringement of patents. In many cases the subjects patented were of a very trifling nature, but still their effect was to shut up the path in that direction from further improvement. The great advance of photography, previously alluded to, and the perfection of the microscope, are chiefly due to the avoidance of patents in connexion with their improvements.

It was found that the instruments exhibited were, for the most part, collected without any concurrence on the part of the exhibitors, for the representation of the state of science in their respective countries, and that therefore it was useless to examine the instruments of each country separately. In the following Report we have, therefore, classified the instruments according to their use, including the contributions of all nations.

It is but right to say that some instruments inserted in the Catalogue have not been found, and that in other cases neither the exhibitor nor any explanation of the instrument were to be met with.

We now proceed to describe the several instruments in each class.

#### *Astr. al. Instru. mts.*

It is to be lamented that this department of the Exhibition contains results of the labours of a few individuals; and of large instruments, with the exception of the great equatorial by Ross, there is none. This circumstance, how much soever a matter of regret, is not one of surprise;—the risk of injury and difficulty of carriage being in some cases almost insurmountable, and the same obstacles existing in full force, with regard to the exhibition of the large class of instruments termed portable. When we consider that, in addition to the above obstacles, the risk of transmission and danger attendant upon removal must necessarily be great, and the involved exposure highly hazardous, the scarcity of instruments in the British, and more particularly in the Foreign Department, will be sufficiently accounted for.

But in those instruments which are exhibited, it is highly satisfactory to find the greater part of them cha-

acterized by exquisite workmanship, and a steady advance in their construction.

In Mr. Ross's great equatorial, it will be seen that he has followed the example of the Astronomer Royal, by having every part of the instrument cast in as few pieces as possible, and has thus avoided all unnecessary screw connections. The casting of this instrument, by Messrs. Ransomes and May, is a fine piece of work. The same principle of casting has been adopted by Mr. Simms, who has avoided various screw connections in the construction of his instruments.

It is most gratifying to perceive that, small as is the number of astronomical instruments, the credit they reflect upon the artists is very great; thus, the instruments exhibited by Mr. Simms possess points of high interest, viz., the conversion of the axis of the transit into a telescope; the modes of illuminating the wires and field of telescopes; the application of the principle of vertical collimation to the altitude and azimuth instrument by piercing the vertical axis; the adapting the axis of an equatorial to the application of a level, &c.,—all of which must be looked upon as improvements, and cannot fail to be of great service for the purposes of observation.

In the German instruments of Merz and Ertel there is exquisite workmanship, well maintaining the celebrated names of the makers of the Pulkova instruments.

The divisions of the Ertel instrument are beautiful; but works of this kind, performed by hand dividing, are operose and distressing.

The practice of hand dividing in this country is now almost superseded by machinery. Mr. Simms' instruments, for the most part, have been so divided. The advantages of this method cannot be better shown than in the comparison of the time occupied by the division of one of the instruments in the Exhibition, the far-famed "Westbury circle," and the time now occupied in performing the same piece of work.

The graduation of the two circles of the Westbury instrument occupied Mr. Simms, as he has informed us, nearly twelve weeks of six days each week, and on an average, of eight hours every day. The work was performed by lamplight, in a room otherwise completely darkened; and although practice enabled him, on subsequent occasions, to accomplish similar pieces of work in considerably less time, yet he always found it to be an exceedingly anxious and oppressive labour. By the means of Mr. Simms' self-acting dividing engine,\* the actual graduation is effected in five hours, to which length of time a period of about five hours is to be added, which is necessarily occupied in the arrangement of the instrument upon the engine preparatory to cutting the divisions. Thus, the same work is done within ten hours which formerly occupied from five to six weeks, not to mention the saving of wear and tear upon the constitution of the operator. The divisions are found to be fully as accurate as those cut by the original process.†

In the American Department, Mr. Bond exhibits the electro-magnetic apparatus used successfully by the Americans, both for the purposes of geodesy and astronomy; this American invention promises to be a real improvement in practical astronomy, and will, in all probability, form a new era in astronomical observations.

DOLLOND (145, pp. 426-428, and see Illustration). A variation transit instrument. The horizontal circle is 12 inches in diameter, on which is fixed a smaller circle of 7 inches diameter; each is divided to every 10', and the larger circle has three verniers, reading to every 10". The

\* This beautiful machine is described in the 15th volume of the Royal Astronomical Society.

† The dividing the 8-foot mural circle at Cambridge, which Mr. Simms graduated on its pier, occupied him several weeks: see the results of the examination of the divisions in the "Cambridge Observations" for 1833; see also the results of the examination of the altazimuth instrument at the Royal Observatory, "Greenwich Observations," 1847; and also the results of the examination of the divisions of the great transit circle lately erected at Greenwich, "Greenwich Observations" for 1851. Both these instruments were divided by Mr. Simms' self-acting dividing engine.

telescopes are 14 inches focal length, and 1.3 inch aperture, with altitude circle and the regular transit series of spider lines, supported upon four pillars fixed to the horizontal circle.

When the instrument is used for determining the actual or diurnal variation, there is a cover containing a lens, which is applied in front of the object glass of the telescope for reading off the divisions on the needles, of which there are two, 7 inches in length, together with various eye-pieces, &c. The instrument is supported on a strong tripod with adjusting screws.

SIMMS (741, pp. 475\*—477\*). A transit instrument, intended for use either in the meridian or prime vertical. The telescope and axis are of the form usually employed for this class of instrument, viz., two stout cones are connected by a sphere into which the cylindrical tubes of the telescope are screwed; the pivots are of hard bell-metal, and are both perforated.

The object-glass has an aperture of  $2\frac{1}{4}$  inches, and a focal length of 42 inches; the diaphragm is furnished with seven vertical and two horizontal spider-lines. There is another vertical spider-line carried by a micrometer screw, and which can be moved completely across the field, so that the distance of an object from any one of the fixed lines may be measured by its means. The lines are adjusted to the focus of the object-glass by a milled head near the eye-end, and another milled head is placed near the axis for the purpose of regulating the intensity of the illumination of the field of view.

The axis of the instrument is converted into a telescope, by having an object-glass fitted into one of the pivots, and a sliding tube carrying an adjustable cross of delicate spider-lines with a positive eye-piece in the other.

The adjustment of this axis telescope is effected by a small collimator placed in a line with the axis—(unless a distinct mark can be seen through it),—and then turning the axis round, and moving the proper screws until the intersection of the lines remain stationary upon the mark, or collimator cross, during an entire revolution. If the principal telescope be adjusted to the meridian, the mark seen through the axis will be  $90^\circ$  distant in azimuth, and by its means the instrument can immediately be placed in the prime vertical, for the determination of the latitude by observation of stars near the zenith. By this invention the form of the pivots may be examined, for if they be not circular, the error will be shown when the cross is being adjusted. The azimuthal adjustment is provided with a micrometer head, showing seconds of arc, so that when the deviation is of known amount, the instrument may at once be placed exactly in the meridian. To take a complete observation of a star in the prime vertical, it is necessary to reverse the instrument, quickly and delicately, for a slight concussion might disturb the adjustments, and consequently vitiate the observation. For this purpose a reversing frame has been contrived and fitted to the base of the cast-iron stand, or support upon which the instrument is placed. It consists of a strong screw having square threads, the circumference of which fits into a cylindrical hole bored through the centre of the stand, and is prevented from turning round by a key which fits into a groove cut longitudinally throughout the length of the screw. The screw is raised or depressed by a pair of bevelled wheels, one of which fits upon the screw, and the other is worked by a winch handle. Above the screw a stage is fixed, and upon this two conical pillars are erected, having a fork covered with vulcanized India rubber upon the top of each of them. Upon turning the winch, the screw is raised, and the forks are brought into contact with the transit axis, and by continuing the motion, the instrument is lifted out of its Y bearings. The frame with the instrument is then, by means of stops, which are attached to the stand, to be turned  $180^\circ$  in azimuth, and then by reversing the motion of the winch, lowered again into its bearings. Two setting circles of 4 inches diameter, and divided to one minute of arc, are attached to the eye-end of the telescope, both of which, previously to an observation, should be set to the zenith distance of the star, in order that no time be lost after reversing the axis, in again directing the telescope to the object.

The stage is forced upwards by means of four spiral springs, which rest upon the base of the stand; these are sufficiently strong to support the whole weight of the instrument when lifted, so that the friction upon the moving parts is very inconsiderable.

The eye-pieces with this instrument are six in number, namely, five direct, magnifying 40, 53, 86, 120, and 140 times, and for zenith observations a diagonal eye-piece, magnifying 90 times.

Mr. Simms also exhibits a diagonal transit instrument of the form used by Reichenbach in his altitude and azimuth instruments. The object-glass is 1.7 inch in diameter, and has a focal length of 18 inches, with magnifying powers of 25 and 45 times. The circle, which is intended for a finder, is 6 inches in diameter; is graduated to show by opposite verniers to one minute of arc; a spirit level is attached to the index of the circle, and there is also a sensitive spirit level for the rectification of the axis. The whole is mounted upon a light cast-iron stand, and is suitable for fixing at a chamber window. In this construction, as is well known, the rays which pass through the object-glass, do not proceed directly to a focus, but are reflected by a prism, or speculum, within the axis, and form an image within one of the pivots, which is perforated, and in which the diaphragm and eye-piece are placed.

Up to the time of Mr. Simms' adopting this mode, no method for the illumination of the field of such an instrument had been devised, except the old one of placing a reflector in front of the object-glass, and throwing light upon it by means of a lamp or candle, in a distant part of the room in which the instrument was fixed. There are several objections to this method:—first, the difficulty of throwing light at all upon the reflector under such circumstances; secondly, the trouble of having to re-adjust it when the direction of the telescope is changed; and thirdly, part of the object-glass itself is cut off by the reflector being placed in front of it. Mr. Simms has very ingeniously overcome these difficulties by lighting up the field of such an instrument, through the opposite pivot to that in which the diaphragm is placed, which obviates all these objections, and effects the object as easily, in this case, as in that of an ordinary transit instrument. The detailed means of doing this are as follows:—

The back pivot, being perforated, has a small convex lens set within it, and a large convex lens of suitable focal length is fixed within the axis, at the back of the reflector; and its diameter is such that one or more segments near the edges (very small segments are sufficient), project beyond the edge of the reflector, and a lamp is placed at the back, with its light directed through the pivot. The action of the lens within the pivot condenses the light, which, after crossing, diverges upon the large lens at the back of the reflector, the open segments of which again condense it upon the field of view, where it produces a full and abundant illumination, that remains unchanged by any variation in the direction of the telescope.

GERARD (109, p. 418) has exhibited a portable or field transit instrument.

The instrument consists of two mirrors, so fixed as to measure an angle of 90 degrees. In use two stations are selected, the one about 100 yards east or west of the other, and on the same level. A mark resembling a target with equidistant concentric circles, is set up at one of the stations, the instrument taken to the other, and so placed as to have the mark in the middle of the field. The telescope is then turned on its own axis till the sun or star is seen by reflection, which will be a few minutes before it passes the meridian. The times of its passing the different circles in succession should be noted. Another set of similar observations should be made at the second station, the mark being set up at the first. The time of the meridian passage will be the mean of all the times at both stations.

DOLLOND (145, pp. 426—428, and see Illustration) has exhibited an altitude instrument, with two circles of 2 feet diameter divided on silver to every five minutes, each circle reading off to seconds by means of two micrometer microscopes attached to the cones which support the instrument. Two small circles are fixed towards the eye-

end of the telescope, each of which reads off the minutes by verniers, with levels for setting the instrument in altitude. The telescope is of 2½ inches aperture and 32 inches focal length, and is fixed between the two large circles. There are five vertical and three horizontal spirit levels in focus of the object-glass, also various eye-pieces, &c.

The instrument is supported in Ys fixed on the top of two strong cones, which rest on a circular metal base, with differential screws for levelling. The usual method of illuminating the webs through the axis of the instrument is adopted. There are also two fine spider lines reading to seconds.

Mr. Dollond also exhibits a double altitude instrument for observing by reflection and direct vision\* (*Cat. supra*). The altitude circles are 1 foot in diameter, divided to 20', and are read off by micrometer microscopes showing seconds. Each circle has a telescope of 15 inches focus and 1·3 inch aperture attached to it, and there are two small circles, read by verniers, for setting the instrument in altitude.

The azimuth circle is 1 foot in diameter, and reads off by verniers to every 10", having a telescope fixed underneath as a check upon the instrument when taking horizontal angles. The axes of the circles are perforated in the usual manner for illuminating the spider lines. The instrument is furnished with fine spirit levels, eye-pieces, &c.

SIMMS (741, p. 476\*). A transit circle, the telescope of which has a focal length of 4 feet, and an aperture of 3·25 inches, furnished with a micrometer in the eye-piece, and magnifying powers of 63, 102, 130, and 165 times. The circle is 2 feet in diameter; it was cast in one piece, of bell-metal. It was divided by Mr. Simms' self-acting engine into spaces of 5' of arc, and subdivided into single seconds by micrometers, of which there are two, fixed to the stone piers which support the instrument.

In addition to the finer graduations, there is another strong circle of divisions, which are cut upon the bell-metal, and numbered to four times 90°, showing either altitude or depression. These divisions are read by a pointer, and they serve to direct the telescope to the object, whether it be seen by direct vision or by reflection.

The Y supports are fixed upon the stone piers. One of the Ys has a vertical adjustment for levelling the axis, which is performed by means of a striding level, and the other has an adjustment in azimuth for adjustment to the meridian. There is also a lever counterpoise fixed to that end of the axis near to which the circle is fixed for the purpose of equalizing the pressure of the pivots upon their respective supports. The instrument is furnished with an embracing clamp, or one which lays hold of the axis, to distinguish it from that kind which bites at the circumference, and also with a tangent screw, which exerts no lifting power, and has, therefore, no tendency to disturb the meridian position of the telescope.

The arrangement for the illumination of the wires is peculiar, and is the invention of the Astronomer Royal; but it was greatly facilitated by adoption of the peculiar method of graduating the light in the field of view, which had been practically introduced by Mr. Simms.

The illuminator, which is, as usual, placed near the centre of the transit axis, and receives the light through one of the pivots, turns upon an axis in order to change its angle of inclination with respect to the eye-piece. By this change of inclination the quantity of illumination is regulated; and if the plane of the reflector be placed perpendicular to the axis of the telescope, no light whatever will be reflected from it. Upon the reflector one or more prisms are so placed as to receive the light from the lamp when the reflector is in darkness. These prisms reflect the light when the reflector is in the position above mentioned, but at no other time, to other prisms, which are fixed in the eye-end of the telescope, near to the diaphragm; and by these last prisms the light is thrown obliquely upon the spider lines, and produces the effect of illuminating the wires on a dark field. To the edge of the reflector a wire is attached, which terminates in a small knob, or handle near to the eye-piece and therefore, near

the observer's hand. The only operation required in passing from one state of illumination to another, with all the intermediate gradations, is either to draw out or to push in a knob or handle through a space of one or two inches.

By these arrangements power is given to the observer to regulate the quantity of light in the field of the telescope, from the faintest gleam, by which the wires are just made visible, to the full illumination, and also to change instantaneously, as circumstances require, a bright field and dark lines to a dark field and bright lines. This change has hitherto been effected by the employment of two lamps, one placed near the perforated pivot to give the ordinary illuminated field, and the other to apply occasionally at the eye-end of the telescope, very nearly in the plane of the diaphragm, so that the light passing through a slit obliquely across the field of view, illuminates the lines which intercept its passage, leaving the surrounding field in darkness. It is clear that the change from one kind of illumination to the other with these arrangements, requires some considerable time, and the hanging a lamp on the eye-end of a telescope of such an instrument as a transit circle is exceedingly objectionable. By the new invention one immovable lamp either illuminates the field or the wires, and the same lamp, at the same time, also illuminates the graduated circle by means of prisms attached to the micrometer microscopes.

This instrument has also another improvement, which was suggested by Mr. W. Simms, jun., since the erection of the transit circle at the Royal Observatory, Greenwich. It is by the perforation of a hole, about one inch and a half in diameter, through the centre cube of the axis, at right angles to the axis of the telescope, in order that a north and south collimator may look into each other without lifting the instrument from the Y bearings, and by this means very much simplifying the act of adjusting the line of collimation.

Ross (254, pp. 435, 436) exhibits a large equatorial. The focal length of the telescope is 18 feet, and the aperture is 11½ inches. The diameter of the hour-circle is 2 feet 3 inches, and that of the declination circle is 2 feet 8 inches.

The instrument is supported on a round cast-iron pillar 10 feet 9 inches in height, 2 feet 3 inches in diameter at the bottom, gradually decreasing to 1 foot at the top. It is formed of two portions, fastened together at the height of 4 feet 6 inches from the bottom of the base, by eight screw-bolts and nuts, passing through flanges, 3 inches in width, from the shaft of the column. This joint affords the means of an approximate meridian adjustment. The base of the pillar is 9 feet in diameter.

The polar axis is of cast-iron, 6 inches in diameter, and 5 feet in length; it is connected to the declination axis by a flange of 18 inches in diameter. The length of the inner male declination axis is 3 feet 6 inches between its bearings; and the outer or hollow axis is 7 inches in diameter. Both are of cast-iron. The inner axis and its flange form one casting with the central hollow cylinder, to the flanges of which the corresponding gun-metal flanges of the telescope are bolted. The tube is of copper.

The fitting bearings of the declination axis are cylindrical, and the axis is secured by a steel collar 4 inches in length, fastened by cross pins to the male centre at the end to which the circle is fixed. In the inner axis there is a counter-sunk cavity to receive this collar, and a second counter-sunk cavity, of large diameter, to receive a steel plate, which is fastened against the end of the steel collar by eight steel screws. By this means the end shake of the axis is adjusted.

The declination circle is of gun-metal, and is regulated by an endless screw, having an eccentric lever attached to a dovetail slide for gearing, and a pair of bevelled wheels at either end for Hooks' joint adjusting rods. There are, also, two other radial arms, with clamp screws, for securely fixing the telescope to the circle.

The upper part of the polar axis fits into a coupling block, having a hemispheric bottom; this is supported by an angular projection from the top of the pillar having a corresponding nearly hemispherical cavity, and the whole is bound together by bolts and nuts, having spherical

\* See "Astronomical Society's Papers," Nov. 24th, 1823.

faces, which bear in corresponding cavities in their washers; the bolts pass freely through the holes.

The lower end of the polar axis is a hemisphere of hardened steel, bearing in a hardened steel dye, surrounded by an oil-cup, which is attached to dovetail slides having motions in rectangular directions, which are supported by a very strong bracket, projecting from the main column, and are applicable to the final adjustment of the polar axis.

The hour circle is moved by a weight and train of wheels, regulated by a Siemen's governor, the ball being suspended by four springs.

This instrument reflects high credit on its maker; it is distinguished by solidity of structure, good mechanism, and distribution of strength.

Also, an astronomical telescope of  $3\frac{1}{2}$  inches in diameter, 42 inches focal length, mounted equatorially. This telescope, on examination, was found to be a very superior instrument, and is the best in the Exhibition for its size.

Also, an astronomical telescope  $2\frac{1}{2}$  inches in diameter, and 30 inches focal length, mounted on a pillar and claw stand.

SIMMS (741, p. 475\*), an equatorial, generally of the Fraunhofer form, with the polar axis elevated for latitude  $25^\circ$ , furnished with a clock motion for counteracting the effect of the earth's rotation. The focal length of the telescope is 7 feet, and its aperture is 4.9 inches: it is furnished with illuminating apparatus, a set of negative eye-pieces, magnifying from 60 to 450 times; a parallel line position micrometer with position circle reading to one minute, and a transit eye-piece, the use of which is to facilitate the general adjustment of the instrument, and also for making observations for time, in the absence of a transit instrument.

The hour circle is 18 inches in diameter, and is read to one second of time by opposite verniers. The edge of this circle is ratcheted to fit the teeth of a screw, which is in connection with the clock before mentioned.

The declination circle is 18 inches in diameter, and is read by opposite verniers to  $5''$  of arc. The slow motion is by an ordinary clamp and tangent screen.

The action of the clock is under the government of a rotatory pendulum, similar to the governor upon a steam-engine.

The only peculiarity in this instrument is in the declination axis, which is not covered up, but open, and exposed between its two supports. The open part is turned cylindrical, and can be set horizontal by a striding level, similar to that of a transit instrument. This construction has several advantages over that in common use; it simplifies the adjustment and the rectification to the meridian, and adapts the instrument for use in the taking of transits, where extreme accuracy is not needed, and greatly adds to the value of the instrument.

Mr. Simms also exhibits a small equatorial, adapted for the latitude of London, but without clock motion. This instrument is upon the same principle as the preceding; it is understood to be inexpensive, but as far as its size permits, it is an effective instrument. The focal length of the telescope is 46 inches, and its aperture  $3\frac{1}{2}$  inches; it carries a parallel line micrometer, with powers of 50, 90, and 150, and the telescope is furnished with an illuminating apparatus. The hour and declination circles are 6 inches in diameter; the former is read by vernier to one second of time, and the latter to one minute of arc, with clamps and tangent motions.

The instrument surmounts an iron pillar, with a tripod stand, and there are screw adjustments, both for elevating the polar axis to the latitude, and for correction to the meridian.

The open declination axis and riding level occur in this instrument as in the former.

DOLLOND (145, pp. 475-477), a portable equatorial, made for the late Capt. Kater, F.R.S. The object-glass of the telescope, which is 30 inches focus, and 4 inches aperture, is worked from a formula of Sir John Herschel's and performs extremely well. The instrument is supported upon a strong folding tripod, is furnished with divided circles, a finder, levels, and a complete set of eye-pieces.

The instrument is well adapted for seeking for comets. SIMMS (741, pp. 475, 476). An altitude and azimuth instrument, known as the Westbury Circle.\* The diameter of the altitude circles is 30 inches, and that of the azimuth circle is 24 inches. The divisions are cut upon a band of silver fitted into each circle, and situated near the circumference. The method adopted in graduating these circles was that invented by the late Edward Troughton, Esq., F.R.S., and described by him in the "Philosophical Transactions,"† as a method of dividing by the eye, to distinguish it from the old method of dividing by the hand.

The circles are divided into 360 degrees, each degree into twelve parts or spaces, and these are again subdivided to single seconds by two micrometer microscopes placed diametrically opposite each other upon both circles.

The microscopes for reading the altitude circle are fixed to the opposite ends of an arm which revolves about an axis concentric with, but perfectly independent of, the axis of the circle, which arm can be fixed in any position at pleasure. This contrivance, which, in effect, is the same as the power of changing the position of the telescope upon the mural circle was, we believe, first applied to this instrument.

The microscopes for reading the azimuth circle are fixed immovably.

The azimuth axis descends within the pier to a depth of nearly three feet, and turns upon a steel point within a conical hole: the upper end of this axis is supported within a rectangular Y by openings opposite the points of bearing, and the axis can be corrected in regard to verticality by adjusting screws, which act upon the frame in which the Y is fixed.

The azimuth circle is screwed to conical radii which spring from the azimuth axis near its upper end.

The altitude axis resembles that of a transit instrument, and the diaphragm is illuminated through one of the pivots in the usual manner. From the central zone of the axis two sets of radiating cones diverge, and to the ends of these cones the circles are screwed, one on either side of the telescope. These circles are connected by cross pieces around the circumference, where they also lay hold of the telescope, which is thus secured against any considerable flexure, and the cones are braced together by two inscribed squares of brass, one upon each face of the instrument.

The object-glass was made by the late Charles Tulley: the diameter of its aperture is  $2\frac{1}{2}$  inches, and the focal length is 36 inches. At the eye-end there is a diaphragm of the ordinary kind, with five vertical and five horizontal spider lines. The eye-pieces consist of both direct and diagonal, furnished with magnifying powers varying from 60 to 150.

The transit axis is adjusted by means of a spirit-level; there is also a spirit-level applicable to the telescope for giving the horizontal point, and a plumb-line apparatus is fixed to the column by which the micrometer support is carried, and serves as a watch upon the stability of this important part of the instrument. The construction of this instrument is light and elegant, and, as experience has shown, it is capable of giving results of a high degree of accuracy; but the modern plan of forming astronomical instruments, of as few pieces as possible, of which Mr. Simms has given specimens in the alt-azimuth and great transit circle at the Royal Observatory at Greenwich, is fast superseding the more elaborate, and if not less accurate, certainly less durable construction.

This beautiful instrument was made by the late Mr. Edward Troughton, at about the beginning of the present century, for Mr. Pond, the late Astronomer Royal, who, by the observations he made with it at Westbury, demonstrated the change of figure of the great mural quadrant then in use at Greenwich. After long exposure to the influence of the atmosphere, and consequent decay, it was in the year 1823 repaired and re-graduated by Mr. Simms, the Exhibitor.

\* For a full description of this instrument, see Pearson's "Astronomy," vol. ii., pp. 419-434.

† See the volume for the year 1809.

**SIMMS (741, p. 476\*).** A portable altitude and azimuth instrument, with circles of 15 inches in diameter, having a telescope of 24 inches focal length, and of 1.9 inch aperture, with two direct eye-pieces, of powers of 35 and 60, also a diagonal eye-piece magnifying 40 times.

This instrument is of the most recent form. A strong brass tripod supports the superior parts, to the centre of which the azimuth axis is fixed, and the azimuth circle is screwed upon its face.

A strong plate circulates upon the azimuth axis, carrying two pillars of massive proportions, by which the altitude circle is supported. To these pillars the azimuth microscopes are fastened, and one of these pillars carries two conical branches, at its upper end, for the purpose of holding the microscopes by which the altitude circle is read, and a sensitive spirit-level is so placed as to detect any instability in these branches, and to give its amount in arc. The telescope and axis are formed like those of a transit instrument, and two circles are on each side of the telescope, braced together with it by intervening pillars.

The circles were graduated upon Mr. Simms' self-acting engine, upon rings of silver, and the subdivision is made to single seconds of an arc by means of two opposite micrometer readings upon each circle. The microscopes of this instrument have achromatic object-glasses.

The transit axis is adjusted by the usual standing level, and each circle is fitted with a clamp and tangent screw motion.

The novelty in this instrument is the introduction of a central collimator, a ready means at all times of determining the nadir point: this important addition is the invention of Mr. Simms.\*

The invention consists in placing a small achromatic telescope in the centre of the azimuth axis, which is perforated for its admission. It is furnished with a cross of delicate spider lines in the focus of its object-glass, and has suitable adjustments.

If the principal telescope of the instrument be directed to the collimator, an image of the cross lines of the latter will be seen upon the diaphragm of the former, and as the collimator remains at rest, being in firm connection with the tripod upon which the instrument stands, it follows that if the superior parts of the instrument be turned round in azimuth, the axis of the two telescopes may, by adjustment, be made to remain perfectly coincident during an entire revolution.

If, in this state of things, the azimuth axis be set truly vertical by means of the spirit-level, which is fixed upon the instrument, the centre of the collimator becomes a nadir point to which all observations may be referred.

This point has additional uses; for instance, in performing the collimation adjustment of the telescope, and in setting the altitude axis at right angles to the azimuth axis, and would consequently supply the place of the transit level, if by accident the latter were broken.

The importance of this invention, especially to the scientific traveller, is obvious; several such instruments have been made by the Exhibitor, which are in use in the Boundary Survey of the United States, and on other similar services.

For the several inventions in these beautiful instruments, the Jury voted, unanimously, the Council Medal to Mr. Simms, which award was also passed unanimously by the Group, but was not confirmed by the Council of Chairmen, and therefore Mr. Simms will not receive that kind of Medal to which the Jury considered him fully entitled.

**CRICKETT (267, p. 437)** exhibits a model of a stand for mounting an equatorial.

**ERTEL AND SON (2, Zollverein, Bavaria, No. 25, p. 1099.)** exhibit a portable universal instrument, with horizontal circle of 15 inches in diameter, and two circles of altitude of 10 inches in diameter. The horizontal circle is divided to two minutes of arc, and is read by two micrometer microscopes to seconds; it is also furnished with four verniers, which read to two seconds. The divi-

sions are fine, clear, and distinct. The circles of altitudes are well divided to four seconds of arc. The two reflectors for illuminating the division under the microscope are so made as to receive light from all sides.

All the clamps are applied to the centre to prevent any bending of the spokes, or affecting the figure of the circle.\*

On fixing the lower clamp, the instrument was found to be absolutely fixed; and in this state was capable of being used as a transit circle. The level was made to rest on three bearing points; it is good; and when placed on the instrument no motion of the vertical circles affected the horizontal fixity of the instrument, or *vice versa*.

The horizontal circle is, in fact, composed of two concentric parts in the same plane;—an inner one, which moves on its own pivot, and revolves, without touching the outer part of the circle, and each moves independently of the other. The centring of these circles is beautiful.

This is a telescope of security, and which has its own motion, and can be set upon any object; and the fixity of the instrument when thus tested was found to be quite satisfactory.

At the intersection of the telescope with its horizontal axis is placed a right-angled prism. By internal reflection at the hypotenusal surface of the prism rays of light coming from the object-glass are reflected towards one end of the axis where the eye-piece is placed, so that in all positions of the telescope the observer looks in a horizontal direction; on the other end of the angle is a graduated circle of 10 inches in diameter, with four verniers (in the same plane as the graduated limb of the circle) each reading to 4". The vernier circle carries a level movable round the axis of the vernier circle, and capable of being clamped to it in any position with the level fixed: a double zenith distance of any object may be observed on one part of the limb. The level may then be fixed in any other position, and the double zenith distance measured on any other part of the limb.

The supports of the horizontal axle of the telescope rise from a strong horizontal piece of metal, to which is attached a vertical steel axis, passing through a vertical cylinder—terminating, below, in a tripod with foot screws. The steel axis carries a horizontal circle, graduated by a line at every three minutes, and also two arms carrying micrometer microscopes. The vernier circle (15 inches in diameter) has a hollow axle which fits on the outside of the cylinder through which the axle of the vernier circle passes, and is capable of being made to revolve in its own plane. Attached to the end of the vernier circle is a cheek telescope with a vertical wire moveable by a micrometer screw.

The vernier circle is graduated by lines at every two minutes. This graduation is read to seconds by each of the two microscopes. The vernier circle being capable of revolving in its own plane, horizontal angles may be measured on different parts of the arcs, by both the verniers and the microscopes. The microscopes have two wires very close to each other parallel to the division in the centre of the field. In observing, the image of the divi-

\* The axle clamp, as used by Troughton, is essentially different from that employed by Ertel. With Troughton it was a matter of convenience: with Ertel it is considered indispensable in order to obtain accurate observation. It is used for the horizontal circle of the Westbury circle, while the more important part, the vertical circle, has a clamp on its limb. In the Westbury circle the extremity of the arm of the clamp is fixed in the direction of its length as well as in the direction perpendicular to its length. This, in the case of the Westbury circle, strains the vertical axle. In the case of a transit instrument, it either bends the axle downwards, or lifts it out of the nearest Y, so that it touches one side of the Y only, or rocks from side to side. In the Munich instrument the axle clamp has a polished surface, which is made to press against the end of a screw by means of a spring or the tension of a spring by which a weight is suspended, and is acted upon by no force in the direction of the length of the arm. I find these clamps recorded as new in notes made during a stay at Munich.—W. H. M.

\* For a full description of this invention, see the 15th volume of the "Transactions of the Royal Astronomical Society."

sion is made equidistant from the two parallel wires. The axle of the telescope has a striding level for determining its horizontality.

Troughton objected to repetition in large instruments. Zach and Bohnenberger had shown that repetition introduced errors larger than those it was intended to correct in well-graduated vertical circles. Struve found that even in the measurement of horizontal angles it was much better to measure the angles on different parts of the arc than to repeat. Accordingly, this instrument is constructed to measure horizontal angles and double zenith distances, but not to repeat. In the older instruments constructed by Reichenbach and Ertel, the circles were made to clamp at their circumference.

In a universal instrument having a horizontal circle of 24 inches diameter (used by Struve as the principal instrument for the triangulation for the Russian arc of the meridian passing through Dorpat), when clamped at the circumference, on turning the slow motion screw the spokes were found to head through an angle of nearly 8" without moving the telescope. In order to avoid this source of error, the clamps are applied to the axes of the vertical and horizontal circles of the instrument.

The heads of the foot screws are graduated; this facilitates the operation of levelling the instrument, and also enables the observer to measure the angle corresponding to a division of either of the levels.

The axle clamps at the extremity most distant from the axle have flat surfaces of polished steel. This surface is pressed by a spring against the point of the slow motion screw. By this contrivance the axle is prevented from rotating, without the danger of straining or bending it, or lifting a horizontal axis out of its Ys, which might happen if the outer extremity of the clamps were fixed, as in the axle clamps that have been used in this country.

It is called a "universal instrument" because it is a transit instrument, and serves also to measure zenith distances and horizontal angles. It is the invention of the firm now represented by Ertel.

The double wires (vertical for the telescope; probably 20" distant from each other) were the line introduced by Reichenbach or Ertel. When a single line is made to bisect a very faint object, the object is extinguished. This is not the case when the object is made to bisect the space between two wires 20" asunder, though it would be if the wires were much closer.

The telescope is diagonal, and consequently only one-half the usual length, the eye, in observation, being always at the axis; and by this means observations can be made in the zenith.

There are on the inner portion of the horizontal circle 10,800 lines; and on the outer portion 7,200, or altogether, 18,000 lines, as fine and distinct as on the largest astronomical instrument. This piece of work alone occupied a fortnight, working many hours daily; and it is a masterpiece of hand dividing.

M. Ertel's objects have been, the combining of the greatest possible simplicity with the greatest possible firmness.

This form of instrument, invented by M. Ertel, has been used with great success in the measurement of the arc of the meridian, by Struve.\*

The Jury voted to Ertel and Son, a Council Medal for this beautiful instrument, which award was sanctioned by the Group; but unfortunately did not pass the Council of Chairmen, who sanctioned the Prize Medal only.

MERZ and SONS (Bavaria, No. 30, p. 1100,) have exhibited an equatorial, with the polar axis adjustable within certain limits, so as to adapt it both as a portable instrument, and applicable to different latitudes within those limits. The focal length of the telescope is 4 feet, and the object-glass has an aperture of 4 inches, a very unusually large aperture for this size of telescope, admitting a large pencil of light, and thus adapting the telescope for faint objects.

It is furnished with powers magnifying 20, 64, 96, and 216 times. It has an hour circle, and a declination circle, both of 7 inches diameter.

The workmanship of this instrument is good, and fully sustains the justly celebrated name of the maker.

The telescope was tried twice; first, by Sir John Herschel, Lord Wrottesley, and Mr. Glaisher, who reported of the object-glass as being first-rate; and secondly, after the lapse of a month, by Sir David Brewster, M. Matthieu, and Mr. Glaisher, whose report was, that the secondary spectrum was not completely corrected, and this appearance was attributed by Mr. Glaisher to a disturbance of the lenses, since the first examination. At the time of the second examination, the image of the sun was good, and the spots on his surface, with their penumbra, were well shown.

A Council Medal was awarded to Messrs. Merz for this instrument.

W. BOND and SON (United States, No. 463, p. 1464,) exhibit an apparatus for observing transits, by means of a galvanic current. It consists of an electric break-circuit clock, a galvanic battery of a single Grove's cell; connecting wires; a cylinder, around which paper is wrapped, and a spring governor, by which a uniform motion is given to the cylinder.

The clock is like those in common use for astronomical purposes. The pallets and the escapement-wheel are insulated, both from the pendulum and from the other wheels. When the battery is in connection, the circuit is broken by the pallet leaving the tooth of the wheel, but is restored at the instant of the beat of the clock, which is in fact the sound produced by the completion of the contact restoring the circuit; the passage of the current being through the pallet and the escapement-wheel alone.

Two wires pass from the clock, one direct to the battery, and the other through the break-circuit key used by the observer, and through the recording magnet, back to the battery.

The electro-magnet, with a slight difference in the form of the armature, is the same as that of Morse's telegraph. The armature carries a glass pen, supplied with ink from a small reservoir. Under this pen the paper revolves, on which the records are made. The breaking of the circuit by the clock, every second, is marked by an off-set made by the pen; and the breaking of the circuit by the observer, is similarly recorded, between the second marks of the clock. Unless a motion perfectly uniform is given to the cylinder, the second marks at the end of the hour, instead of being arranged in regular straight lines upon the paper, will change their relative positions. Uniform motion is given to the cylinder by means of an apparatus called a spring governor. The train of wheels which communicate the motive power to the cylinder is connected with a small fly-wheel. This fly is for supplying momentum, and near it is placed a half-second's pendulum, with a dead beat escapement. The connection between the escapement-wheel and the fly is through a short spring. The elasticity of this spring allows the motion of the escapement-wheel to be completely arrested at each vibration of the pendulum, while the momentum of the fly, acting for a small fraction of a second only on the spring, keeps up the motion of the cylinder.

The cylinder revolves in one minute; the second marks in a continuous spiral.

In observing, the observer, with the break circuit key at the instant of the transit of a star over the wire of a telescope, touches the key, and the record is instantaneously made on the paper.

In the ordinary method of observation of transits, the observer listens to, and counts the beats of a clock, whilst his eye is directed to the object passing the wires; thus he combines the two senses, of hearing and seeing, in such manner as to be enabled to compute, mentally, the fraction of the second when the object passes every wire, the time of which he then writes down in an observing book, still listening and counting the beats of the clock, and so on till the object has passed all the wires. In this new method, he observes with his eye the passing of the heavenly bodies, and at the same instant touches the break circuit key; with this apparatus it is evident that a

\* For a description of this instrument, see "Description de l'Observation Astronomique Central de Poulkova," par F. G. W. Struve, and also the "Recueil des Actes," pour l'année 1834.

signal almost instantaneous in duration can be recorded, by the momentary interruption of the circuit.

The practicability of this method of recording observations is placed beyond a doubt by experience in America, and from the results there obtained, this method would appear to be more accurate than that usually adopted by the combination of the eye and ear. The question yet remains to be determined, whether there be a closer connection between the nerves of the eye and the ear, or between the nerves of the eye and the finger, and this question can be settled only by experiments.

The Council Medal has been awarded to Messrs. Bond.

#### *Nautical Instruments.*

Exhibitors of nautical instruments are few in number, and, with the exception of those exhibited by Ericsson (United States, No. 146, pp. 1442-1446), and those by St. John (United States, No. 95, p. 1439), display but little novelty, and no decided improvements.

The sea-lead and the several other instruments exhibited by Mr. Ericsson, reflect high credit upon him: they are original in their design, well adapted for their work, and useful.

#### *Nautical Astronomical Instruments.*

SIMMS (No. 741, pp. 475\*, 476\*), exhibits a Troughton's reflecting-circle, 10 inches in diameter, with three equidistant verniers reading to 20" of arc, having an achromatic telescope with eye-pieces magnifying 8 times and 15 times, supported upon a counterpoise stand, with motions for placing the instrument in a vertical, oblique, or horizontal plane.

This instrument was invented by the late Edward Troughton, and was designed as an improvement on the reflecting-circle, previously in very general use. With it, a cross observation gives six readings upon the circle, which is perhaps as high a degree of accuracy as is attainable by any instrument held in the hand, and such an observation is obtained with much less labour than one claiming equal confidence upon the ordinary repeating-circle.\*

Mr. Simms also exhibits a Troughton's sextant (p. 477\*), fixed upon a counterpoise stand; this instrument was contrived for the purpose of combining strength with lightness, and consists of two thin frames of brass, united by pillars. This form was suggested to the inventor by his having observed, that with one of the large open-framed sextants, a contact of the sun's limbs made with the telescope directed upwards was but apparent, a large space occasionally intervening when the telescope was directed downwards into an artificial horizon.

This form of sextant has not only maintained its ground, but would appear by those exhibited to be fast verging on general adoption. It is usually made of 8 inches radius, and is divided to 10" of arc.

A Prize Medal was recommended by the Committee upon Sextants for these instruments of Mr. Simms.

BARRETT (No. 349, p. 449) exhibits several sextants, one of which is furnished with a magnifier, prepared for reading without shadow by night; the instruments are for the most part of an ordinary character, nevertheless Honourable Mention was awarded to Mr. Barrett.

Crichton (No. 452, p. 462,) exhibits many sextants, some of a very ordinary kind; there are two, however, numbered 2251 and 2252, which are well made, but the divisions on the vernier and on the limb do not agree in any of them. In connection with drawing instruments, &c., a Prize Medal was voted to Mr. Crichton.

Mrs. JANE TAYLOR (No. 350, p. 449,) exhibits a sextant intended rather for show than use. Other exhibitors of sextants are ELLIOTT and SONS (No. 322, pp. 464-466), WATKINS and HILL (No. 659, p. 438), and DIXEY (No. 271, p. 466\*).

MONTENI and SIEGLEW (France, No. 649, p. 1209, exhibit sextants and reflecting circles, pretty good in all

respects, the divisions excepted. The Jury awarded these instruments Honourable Mention.

VEDY (France, 719, p. 1213,) has exhibited a reflecting Borda's circle divided to 20', and read by means of verniers to 20". A reflecting circle made after the improvements of Captain Richards, by means of which very large angles may be measured.

A sextant read by verniers to 20"; another divided to 10', and read by a vernier to 10"; a third and fourth, reading to 15"; a fifth, whose reading is to 30"; and a sixth, which reads to one minute. M. Vedy also exhibits an artificial horizon. These instruments are well made, and a Prize Medal was awarded to M. Vedy.

BURON (France, No. 443, p. 1199) has exhibited various sextants and octants in ebony and brass, furnished with coloured glasses to the number of five or seven, and with both direct and inverting telescopes. The sextants are divided to 10', and subdivided by verniers to 10". The size and the construction of these instruments are in every respect like those made in England. Their divisions are good, and their price is low.

BEAULIEU (Belgium) exhibits a sextant of 7.5 inches. The graduations are on silver to 10", sexagesimal, with every means for verification. The body of the instrument is in one piece, and is very solid; a second sextant of the same size, divided, &c., as the preceding; another sextant of 6.3 inches radius, furnished with the same accessories as the preceding, and reads to 15" sexagesimal; a fourth sextant of 4.3 inches radius, divided to 20" sexagesimal, a fifth sextant of 2.8 inches radius, divided on silver to sexagesimal minutes; a sixth sextant of ebony 9.4 inches radius, divided upon ivory to 30" sexagesimal; also an octant in ebony of 10.6 inches radius, divided on ivory to sexagesimal minutes, and two artificial horizons. The sextants are solid and well made, and the work of all is good.

A Prize Medal was awarded to M. Beaulieu.

OERTLING, A. (Prussia, (1) No. 87, p. 1053,) exhibits sextants whose divisions on the limb are faint, but good; the verniers are such that it is difficult to judge of the reading to 10" in the larger, and to 16" in the smaller sextants.

IMPERIAL JEWELL WORKS (Russia, No. 169, p. 1372,) exhibits two of the largest sextants in the Exhibition, being 10 inches radius. These are sound and well made, and reflect credit upon the artists.

ASKE (No. 194, p. 431) exhibits an instrument for determining the course which a ship must steer to sail on a great circle. That the instrument will do its work is more than probable; but whether it has any advantage over the published tables for the same purpose is more than doubtful.

#### *Various Nautical Instruments.*

ERICSSON (United States, No. 146, pp. 1442-1446,) has exhibited a sea-lead. This instrument, which is designed for making soundings at sea, independently of the length of the lead line, and without the necessity of rounding the vessel to the wind, is a modification of an instrument formerly constructed in conjunction with Mr. Ogden, of Liverpool.

The instrument consists of two large tubes; a chamber is placed immediately behind, and connected by means of a small bent orifice to the upper extremity of one of them. The top of the second is connected by a similar orifice to a third small tube suspended in the centre of the chamber. A stop-cock is placed at the lower end of the glass tubes for the purpose of cutting off communication, if necessary.

The lead being bent to the line is lowered into the sea, as it sinks, the water enters the chamber, and gradually rising in it and in the tube suspended within, causes an increased pressure upon the air, which is driven through the orifices into the glass tubes. The tube which is connected with that in the chamber will be entirely filled with the air thus forced into it from the suspended tube, the water will consequently rise, and its reading may be observed upon the graduated scale with which the instrument is furnished for that purpose.

The contents of the chamber being much greater than

\* For a full description of this instrument, see "Pearson's Astronomy," and "Encyclopædia Metropolitana," vol. i, p. 638.

that of the tube suspended within it, the air with which it is filled will not be compressed sufficiently to admit water into the glass tube connected with it until the lead shall have descended to a depth of 25 fathoms. This tube is therefore well adapted for the measurement of deep soundings, whilst the other registers small depths, which otherwise could not be indicated. This instrument in its use is attended with less loss of time than the casting of the ordinary deep-sea lead.

Mr. Ericsson has exhibited an instrument for measuring distances at sea. This instrument is intended chiefly for the use of naval officers, to enable them to determine, by means of a single observation taken at sight, the distance of a vessel, either advancing to or receding from the observer.

If the eye be placed at a certain height above the level of the sea (say on the main-top of a ship), the vertical angle, formed by a line passing from the eye to any fixed point in the horizon, and a line from the eye to the water line of the hull of a vessel in the distance, will become greater as the vessel approaches to, and will become less as the vessel recedes from, the spectator; to measure this angle and to determine the distance of the ship, is the chief purpose of this instrument, which is composed of the following parts:—

An ordinary reflector, an object-glass, and a sight for measuring angles. The reflector is attached to the end of a spindle which is turned by means of a lever. At the lower end of this lever, in a slot, a sliding nut moves freely up and down, in which a thumb-screw is made to work. A pinion on this screw works into cogs cut in the circumference of a graduated index-plate, which is supported upon a frame, and revolves by means of a socket in a centre piece. The scale of the index-plate is graduated into yards for every variation of distance of 10 yards, from the horizon to 400 yards distance from the ship, as viewed from an elevation of 100 feet. For these and the other beautiful instruments exhibited by Mr. Ericsson, a Prize Medal was awarded to him.

KELLER (France, No. 280, p. 1190) exhibits a double planisphere, designed to assist navigators in great-circle sailing. It consists of two concentric circles, the one fixed and transparent, the other moveable.

ST. JOHN (United States, No. 95, p. 1439) has exhibited a very ingenious self-detector compass. In appearance it is very similar to the ordinary box-compass, and differs chiefly in the following particulars:—upon the compass card, and attached to it by pins, are two small needles, called satellites; to the centre of each a brass indicator is fixed; on the face of the card are engraved two semi-circular scales, or arcs of circles, so placed that their centres are in the centre of the compass card, and in a line joining the centres of the satellites: both these scales are graduated to degrees, the numbering of the graduation proceeding on either side from the central point of each scale. The satellites are balanced upon pins, move freely, and thus permit the brass indicators to move easily over the graduated arcs, according to the amount of disturbance. The satellites and the main needle being equally magnetized, remain stationary when there is no cause of disturbance in the magnetic meridian, and the brass indicators point to their respective centres; but, should there be any cause of disturbance, the indicators move simultaneously in opposite directions, thus indicating its amount, and if the course of the disturbance be local, the indicator attached to that needle, the nearest to the seat of disturbance, will pass through the greater angle, and thus the direction of the disturbing cause is shown.

Mr. St. John has also exhibited an aquatic velocimeter. This instrument is designed to show upon a dial-face the distance traversed by a vessel in a given time, and its velocity. Upon the dial are three circles, each provided with an index, and so graduated that the first performs one revolution in a mile, the second in 100 miles, and the third in 1,000 miles. The motion is communicated to the clock mechanism by means of several mechanical adjustments, within a tube, which is inserted in the bottom of the vessel, and protected from injury by a coating of India-rubber, and a wooden box, by which it is completely enclosed. The chief part of the mechanism consists of a

revolving shaft, which receives its motion from a paddle-wheel attached to it. The water acting upon its fans causes it to turn round, the shaft in connexion with it performing one revolution in a distance of 4 feet. The arrangement also includes a metal frame; and pistons to obviate any danger which might arise from the position of the pipe within the vessel; there are also facilities for disconnecting the apparatus from the clock-work, for the purpose of setting the index to any time or point desired. This instrument is new, and seems to be well adapted for its work. The Jury consider much merit due to Mr. St. John for these inventions, and award the Prize Medal to him.

#### *Surveying Instruments.*

The instruments exhibited in the British portion of this section are few in number, and, with the exception of those by Simms, Dollond, Marratt, and Yeates, are, for the most part, of an ordinary kind, there being neither improvement nor attempt at such in their construction.

In the Foreign Department it is otherwise. In Belgium may be found Benoit, worthily following in the steps of his celebrated master, Gambey. In Germany, Brithaupt's admirable method of covering the divisions of the circle by a thin circular plate seems to be generally adopted, and commands attention. The further improvements which he has introduced in his surveying instruments will be detailed presently.

The Polytechnic Institute of Vienna has exhibited various instruments for levelling, which present many improvements, the result of more than an ordinary degree of attention. Mr. Burt, of America, has exhibited a compass well adapted for surveying.

#### *Surveying and Levelling Instruments.*

SIMMS (No. 741, p. 476) exhibits a transit theodolite. This kind of instrument was introduced a few years since by Mr. Simms; it is intended especially for the use of the scientific traveller and civil engineer. It is, in fact, an extremely portable altitude and azimuth instrument. The ordinary vertical arc of the theodolite is extended to a complete circle, and is read by two opposite verniers. The range of the telescope is unlimited, like that of a transit instrument, and by means of a diagonal eye-piece, observations can be made in the zenith. The axis is perforated for illumination of the field of view. The instrument is 8 inches in diameter; it is graduated in silver to 10" of arc; its readings are by means of verniers. By estimation the angle can be read to less than 5".

The telescope is 73 inches in focal length, and 1½ inch aperture, and is furnished with magnifying powers of about 25 and 40 times. The magnetic needle, spirit level, lamps, and tangent screws, and other fittings, do not differ materially from those usually adapted to theodolites of the best construction.

DOLLOND (No. 145, pp. 426—428). A transit theodolite. The circles are 12 inches in diameter, each reading by verniers to every 10' of arc. The telescope fixed to the altitude circle is 20 inches focal length, and 1.6 inches aperture, furnished with direct and inverting eye-pieces, and is supported on Ys, on two strong cones resting on the azimuth circle. The compass is 5 inches in diameter and divided to every degree. The spider lines are illuminated in the usual manner through the axis of the altitude circle.

YEATES (No. 332, p. 446) exhibits a very portable small theodolite, with good divisions, well made, and strongly put together. It is furnished with one large spirit level. Also a 4-inch theodolite, displaying good workmanship; a prismatic compass with a spirit level attached, and an optic square, intended for use in determining distances. All these instruments are well made, and deserving of Honourable Mention.

MARRATT (No. 409, p. 554) exhibits a 7-inch theodolite, which reads to 15". It is furnished with a locking-plate and tripod. The lower portion consists of a massive tripod with foot-screws, to which is fixed the centre on which the instrument revolves. The lower limb is in one piece, and is furnished with tangent-screws and three verniers. The exterior centre and Ys for the support of

transit axis are cast in one piece, and to which is attached a spirit level. The telescope is soldered to the axis, and the vertical circle is firmly screwed to it, so that the vertical circle, axis, and telescope, are firmly connected. The whole instrument is formed of the smallest number of pieces, with the view of preventing flexure and insuring stability. The Jury awarded Honourable Mention.

JOSEPH (Canada, No. 182, p. 968) exhibits a 6-inch theodolite of very indifferent workmanship.

ELLIOTT and SONS (No. 320, p. 444) exhibit an altitude and azimuth instrument of the ordinary construction. It is understood that this instrument is intended chiefly for surveying purposes; it is coarsely divided. They also exhibit two transit theodolites, the one of 5 inches and the other 6 inches diameter. These instruments were not adjusted. Messrs. Elliott and Sons also exhibit dumpy-levels of good workmanship. In those exhibited, the index-bar on which the level rests is placed vertically, instead of horizontally, as they were in those by Mr. Garratt, the inventor of this kind of level. There is also a change in the mode of adjusting the bubble; instead of the use of three screws at either end of the bubble, there is one strong joint at one end, and a screw at the other; the joint cannot move till the screw at the other end is loose, and it is so constructed that it is almost impossible to become loose by travelling; and they exhibit an instrument based upon the principle of similar triangles, adapted for the determination of distances.

BRIDGES (No. 339, p. 448) exhibits an instrument to determine the distances of objects, either by night or by day, and rules are given to determine the distance when the height is known, or when its breadth is known, or when neither is known, and also to determine the same by night.

BARTON (No. 708, p. 473\*) has exhibited an instrument designed for sketeling ground, for military purposes, with great rapidity. It is designed with a view to its being manageable in the hands of men engaged in military service, without regard to their scientific acquirements. Its simplicity of construction renders it very inexpensive.

For description of this instrument, see *Illustrated Catalogue*. Honourable Mention is given to this exhibitor.

JADDELL (No. 362, p. 450) has exhibited pocket-sight and field-sight spirit-levels to the number of 31, as used by mechanics, and adapted for drainage, road surveying, &c.

The spirit-levels are exhibited on account of lowness of price; some of the sight-levels are furnished with reverse sights; there is one level with a revolving shade, intended as a safeguard to the level tube.

ADCOCK (No. 353, p. 449) has exhibited a machine for drawing and mapping roads.

GREEN (No. 446, p. 462) has exhibited a miner's compass.

COX (No. 347, p. 449) has exhibited a beam draining level, with adjusting parallel plates on tripod stand. It is a simple and inexpensive instrument, giving, by inspection, the rise and fall of land intended to be drained. It is also useful in laying tiles, levelling, and in building operations. Mr. Cox has also exhibited an A level, to be used without either parallel plates or tripod stand.

BLVTH (No. 367, p. 450) exhibits four levels, of different lengths, with stand and small telescope.

DOBBS (No. 346, p. 449) exhibits a spirit-level, applicable for levelling machinery.

HORNE, THORNTWHAITE, and WOOD (No. 220, pp. 434, 435) exhibit an angular spirit-level, showing the rise and fall in inches and parts. It is adapted for agricultural purposes.

DENTON (No. 317, p. 443) exhibits a workman's draining A level, with a bob, intended for the use of farm labourers; and a second level of the same construction furnished with a spirit-level.

WILTON (No. 402, p. 453) exhibits a miner's theodolite.

BURON (France, No. 443, p. 1199) exhibits a repeating theodolite with concentric circles, 8.7 inch diameter, divided to 10', and read by four verniers to 10". It is furnished with two telescopes of 17.7 inches in length, and apertures 1.2 inch. The vertical circle is 4.3 inches in diameter, and is divided to 30". Mr. Buron also exhibits several levelling instruments.

BEAULIEU (Belgium) exhibits a repeating theodolite, of

the form used by Gambey. Its circle is 13 inches in diameter, divided on silver to 10 centesimal minutes, read by means of four verniers to 10 seconds, and is adapted to take either horizontal or vertical angles.

The azimuthal circle is 8.7 inches in diameter. It is divided upon silver, and is read by a single vernier. It is furnished with two levels. The telescope is 1.8 inch aperture, and 12.8 inches focal length. There is a counterpoise attached, to be used when vertical angles are to be taken. This instrument was constructed for the *Dépôt de la Guerre*, in Belgium, for which service all the instruments are divided upon the centesimal system, but M. Beaulieu has likewise divided this instrument sexagesimally, the principal circle reading to 4 seconds of arc, and the azimuthal circle to 20 seconds. All the divisions of this instrument are very good, as indeed is the workmanship of the whole instrument, and the sextants exhibited (see Section, Nautical Instruments); a Prize Medal was voted to M. Beaulieu.

GROENEAERS (Belgium, No. 156, p. 1156) exhibits an instrument for determining the distance of inaccessible objects. It is stated that the results obtained by the use of this instrument have been good.

DE HENNAULT (Belgium, No. 183, p. 1157) exhibits a miner's compass, intended for use in determining the co-ordinates of a mine.

LAURENT (Belgium, No. 185, p. 1157) exhibits a small miner's compass, but not so well made as the preceding.

BECKER (Netherlands, No. 83, p. 1147) exhibits a levelling apparatus.

BREITHAAPT (Prussia, No. 670, p. 1087) exhibits a theodolite. In this instrument, as in most theodolites of German make, the circle which carries the verniers is let into, and surrounded by, the graduated circle, so that their upper surface, on which the graduations are traced, are in one plane. In order to protect the divisions from dirt, rain, and from mechanical injury, the vernier circle carries a thin circular plate of brass, which completely covers the graduated or outer circle, with the exception of two openings, covered with plate glass, through which the verniers can be seen.

This useful covering for the graduations, though now used by other artists, was, we believe, first introduced by Mr. Breithaupt.

Mr. Breithaupt also exhibits a level, which instead of having circular collars on the telescope, which it is difficult to make of equal diameter, and, if accurate when the instrument is new, are very apt to bear unequally, has towards each end of the telescope a knife-edge, and opposite to it, on the other side of the tube, a steel screw with a convex head; one knife-edge is on the upper side of the tube and one on the lower side. The level is attached to a plate of steel, having its under surface ground truly plane. By turning the convex-headed screws, the planes through the knife-edges, and touching the heads of the screws, can be made parallel to a line joining the centre of the object-glass and the intersection of the cross wires, and therefore to each other. The line of collimation of the telescope will be truly horizontal when the bubble of the level maintains the same position before and after inversion. This contrivance greatly increases the facility of adjusting a level, and of rendering the person using it independent of the skill of the maker.

It is a common error among surveyors to assume that the circular collars of a level are of equal diameter; and as long as this belief prevails, this invention must be of peculiar importance.

Mr. Breithaupt also exhibits a mining theodolite. This instrument is attached to its tripod by a slightly conical socket, and the graduated circle is made horizontal by two screws, opposed by two strong springs. The graduation of the horizontal circle is to 30" and has two verniers. Its diameter is nearly 4½ inches. The vertical circle, which is about the same diameter, is also read to 30" by two verniers.

The telescope, whose aperture is about 11 lines at the place where it meets the horizontal axis, has a right-angled prism, which reflects the rays coming from the object-glass. At one extremity of the long horizontal axis are placed cross wires, adjustable by rack and pinion,

and an eye-piece, adjustable by screwing, similar to those of the levels. The telescope can be pointed to any object, from the zenith to a depression of  $50^\circ$  or more below the horizon, and can be clamped, at any altitude, to an arm which is moved by a micrometer screw; and thus distances can be measured from one station, by observing the altitudes or depressions of two fixed marks on a staff. A level, like that of the transit instrument, is applied to the axis of the telescope. (Prize Medal awarded.)

LÜTTIG (Prussia, No. 81, p. 1053) exhibits a levelling protractor, the divisions of which are good.

KINZELBACH (Bavaria, No. 26, p. 1115) has exhibited a surveying cross, being a cone of brass, with two pairs of fine slits, for sights, at right angles to each other, running obliquely up its sides, and revolving on a base, the circumference of which being graduated, is read off with a vernier, the whole being screwed on the top of the surveyor's rod.

Mr. Kinzelbach has also exhibited a diastimeter, or distance-measuring instrument; being a telescope, provided with a micrometer and divided scale, the micrometer being mounted with two parallel wires, moveable simultaneously along a scale, graduated to minutes, so as to remain at equal distances from the centre of the field of view, and thus to embrace the area of greatest distinctness in all cases. Also an improved Wollaston's goniometer.

IMPERIAL POLYTECHNIC INSTITUTE OF VIENNA (Austria, No. 130, p. 1014) has exhibited several beautiful instruments, constructed according to the plan suggested by Professor Stampfer.

1. A large level.\* The aperture of the object-glass is 15 lines, and the power 20. The support of these levels consists of three feet, attached to the sides of a triangular prism by strong screws. The upper part of the prism is a truncated cone, fitting into a slightly conical socket, which forms the lowest part of the brass-work of the level. This socket is clamped very firmly on the stand by a single turn of a screw, so that the level can be readily attached to, or removed from, its tripod. The lower part of the level consists of two circular plates, connected by a ball and socket, as in the levels constructed in this country. But instead of four screws for making the upper plate horizontal, the Austrian level has two screws and two strong springs, the screw being at one end, and the springs at the other end of each of two diameters of the plates, at right angles to each other. By this contrivance the upper circle is more quickly and easily made horizontal than in many other known instruments of this kind, without the danger of either shaking or bending the plates, attendant upon the use of four screws.

The upper circle, which is about  $4\frac{1}{2}$  inches diameter, is graduated, and has two verniers, reading to  $30''$ .

The greatest improvement introduced into this level is a micrometer screw, by which an angle in a vertical plane, if not more than  $8^\circ$ , can be determined to within  $1''$  or  $2''$  of the truth. This screw is of great use in making the telescope very accurately level, when the instrument is employed in the ordinary manner, and the situation of the levelling staves so chosen that they are intersected, at some point of their length, by a horizontal plane through the axis of the telescope. By the aid of the micrometric screw, however, the difference to the altitude of two stations can be determined, when it greatly exceeds the length of the levelling staff. For this purpose the staff carries two marks, at a known invariable distance from each other. The angular altitudes or depressions of these two marks, measured by the micrometer screw, serve to determine, with great precision, not only the inner elevations or depressions of either mark above or below the axis of the telescope, but also its horizontal distance from the centre of the instrument. These distances, combined with the difference of azimuth of the stations observed with the horizontal circle, afford data for constructing a map of the country passed over in levelling. The selection of stations in this mode of levelling is limited only by the condition that the elevations or depressions of the marks shall not exceed  $8^\circ$ . By one observation, differences of level of 100 feet between two stations may be measured;

thus the stations may be taken at much greater distances from each other than in levelling by the old method. This advantage is particularly felt in levelling through a hilly country. By means of this instrument the altitudes of distant objects may be measured with great precision.

The telescope is adapted to the distance of the object observed by a sliding tube carrying the cross wires, moveable by a rack and pinion. This tube moves between three bearings, attached to the inside of the outer tube, at equal distances from each other; one of these is a spring wheel, which, by its constant pressure, prevents all shake of the tube carrying the micrometer. The telescope is adapted to the focal length of the eye of the observer, by having that lens of the eye-piece which is next the eye set in a cap, which screws on the end of the tube, and by turning it is brought to the proper distance, to give distinct vision of the cross wires.

2. Smaller levels, of similar construction, in one of which the telescope has a power of 15. In another the power equals 12. A fourth is similarly constructed, with the exception that it has no horizontal graduated circle: the power equals 6.

3. Two pocket telescope levels.

4. A ruler for plane table surveying, with a telescope provided with a micrometer screw, similar to that of the large levels for measuring distances.

5. A ruler for plane table surveying, with telescopic sight. The Jury awarded Honourable Mention for these instruments.

SCHRÖDTER (Prussia, No. 484, p. 1078) exhibits a 6-inch theodolite, of very good workmanship. The Jury awarded Honourable Mention to Mr. Schrödter.

IMPERIAL LORISK WORKS (Russia, No. 169, p. 1372) exhibit a levelling instrument, mounted on a well-braced and very firm tripod stand. The instrument is well made in every part, with good divisions, and reflects credit upon the artist.

BURT (United States, No. 187, p. 1449) has exhibited an "astronomical compass," an instrument intended for the survey of lands, bays, &c., for the determination of latitudes, apparent time, and the magnetic declination.

It consists of two plates of about  $6\frac{1}{2}$  inches in diameter: the upper revolves about the lower by means of a centre-piece, which, when fixed, leaves the under plate to revolve freely. The two plates can be clamped together by means of two clamps. The upper side of the lower plate is divided, the graduations being seen through two openings in the upper plate, and which are furnished with verniers. A small magnet is placed on the upper plate for determining the declination. To the upper plate is fixed a grooved arc, a latitude arc, a declination arc, an hour arc, two spirit-levels, &c. The latitude arc is fitted to one end of a curved bar, the other end of which is in connection with the hour arc, and can be adjusted to the latitude of the place. The declination arc is placed upon a limb which revolves equatorially upon a centre, and there is a second moveable limb turning on a pivot at one end, and furnished with a vernier at the other, which moves on the declination arc and affords a means of clamping it to the sun's declination. To each end of a moveable brass limb a small brass plate is attached at right angles; into the upper side of one, and to the lower side of the other, a small convex lens is inserted, fitted with a sliding shade, through which there is a small hole; opposite to each lens is fixed a small silver plate; on these plates fine lines are drawn, sufficiently separated to include the image of the sun. The arcs of latitude and declination have each a radius of 5 inches, and are graduated to  $15'$ , and read by verniers to single minutes. The hour circle has a radius of  $2\frac{1}{2}$  inches, and is divided to half degrees. The instrument is furnished with every means of adjustment and verification. It is well adapted for surveys in new districts, and has rendered good service in magnetic districts, where it is understood that instruments constructed with magnetic compass have failed. The Jury voted a Prize Medal to Mr. Burt.

#### Standard Measures of Length.

WHITWORTH and Co. (Class VI., No. 201, p. 290) have exhibited a standard bar measurer. This machine consists of a metal frame, at each end of which is placed a micro-

\* See the 20th volume of the Polytechnic Institute.

meter; that to the right-hand is a combination of a screw about ten threads to the inch, of a tangent screw and wheel with 400 teeth, and also a circle with 250 divisions. Therefore the divisions on the circle indicate  $\frac{1}{250}$ th of  $\frac{1}{400}$ th of an inch, or of one millionth part of an inch. The micrometer placed at the left-hand is furnished with a screw with ten threads to one inch, and a circle divided into 500 parts, and thus one part of the circle corresponds to  $\frac{1}{500}$ th part of an inch. On the upper side of the frame, and extending through its whole length, is placed a half square groove made of steel, with its angle downwards, and its upper edges horizontal. In this the measure is placed. Between one end of the measure and the point of the right-hand micrometer, a perfectly flat contact piece of metal is placed, with its sides parallel; the other end of the measure abuts against the left-hand micrometer.

There are two methods of determining when contact takes place, and hence the length of the standard measure.

1. By that which is termed the test of gravitation.
2. By that which is termed the galvanic test.

(1.) The test by gravitation is as follows:—

The experimenter moves the end of the screw of the right-hand micrometer through one millionth of an inch, by means of the right-hand micrometer; then carefully raises the contact piece, and allows it to fall by its own gravity: he then moves a screw through a second millionth of an inch, raises the contact piece as before, and so on, till the approach of the end of the micrometer screw to the end of the measure prevents the contact piece from descending. This completes the measure.

(2.) The galvanic test is as follows:—

There is a small battery composed of a piece of zinc and copper soldered together and immersed in rain water, without the admixture of any acid; this is connected with the micrometer (which is insulated from the machine), and with a delicate galvanometer by means of covered wires. The measure itself is also insulated from the machine.

By pursuing the same process as before, contact is indicated on completing the circuit by the deflection of the needle of the galvanometer.

This beautiful and delicate apparatus seems to be capable of improvement: the ends of the measure exhibited are perfectly flat, and of its full size; the contact pieces are somewhat smaller, but the constant and repeated contact must wear the ends away, and soon alter its length. For a standard bar, it would certainly be better to insert at its ends a smaller contact surface, of a substance much harder than steel. A Council Medal was awarded to Messrs. Whitworth. (Awarded also in Class VI.)

BAUMANN (Prussia, No. 76, p. 1052,) exhibits Bessel's standard measure. It consists of a solid beam of mahogany 4 feet  $6\frac{1}{2}$  inches in length (Prussian measure), 7 inches 2 lines square. The two 3-foot bars to be compared are placed upon a carriage on five wheels, which run on rails in a direction at right angles to the length of the bars. At each end of the carriage are receptacles for the bars with screw adjustments for placing them in a proper position for comparison. At each end of the beam is placed a micrometer, consisting of a slider moved by a screw having about 400 turns to the inch. On the slider are two  $\frac{1}{2}$ s, in which rests a cylinder of steel about 7 lines in diameter, and  $\frac{1}{4}$  inches long. The inner end (viz., the end directed towards the middle of the beam) is ground convex, the other end is a cone. The point of the cone rests against a vertical plane of steel attached to the axis of a "fühlhebel" (lever of contact) at a point about 0.25 inches from the axis. The bars to be compared (bars of steel, not hardened, 0.75 inches square, having their ends on rather a small circular disc at either end, which is made of hardened steel, ground truly plane), are placed on the carriage, with their axis about 14 inches asunder. The carriage is moved till the axis of one of the bars coincides with the ends of the steel cylinders, and the micrometer screws are turned till the convex end of the steel cylinders coming in contact with the end of the bar, the pointed end of each cylinder pressing against the steel plate attached to the axis of the level turns the level, till the bubble rests nearly in the middle. The divisions of

the head of the micrometer screws, and the divisions of the level scales at which the end of the bubbles rest, are then read off. The slides are now withdrawn through a small space, the carriage moved till the axes of the second bar coincides with the axes of the steel cylinders, and the micrometer screws turned as before, till the convex ends of the cylinders come in contact with the ends of the second bar, the conical points turn the level till the bubbles rest nearly in the middle of the scale, the divisions of the heads of the micrometer screws and divisions at which the ends of the bubbles of level rest are read off. This constitutes one comparison.

After a certain number of comparisons have been made in this manner, each bar is turned, so that the surface which was undermost becomes uppermost, without turning either of them end for end, and the same number of comparisons made as in their original position. The object of this is to estimate any error that might arise in making the ends of the bars coincide with the axes of the two steel cylinders, supposing the plane end of the bars not to be exactly at right angles to the axes. During the comparisons the bars are covered by a wooden case, which allows the heads of the micrometer screws and tubes of the levels to be seen, and has two openings, covered with glass for observing the thermometers placed on the bars to be compared.

The delicacy of this "comparateur" is such that unless extraordinary precautions be taken, the errors produced by the fluctuations of atmospheric temperature are much greater than the errors of measurement.

In order to eliminate error, arising from the heat radiating from the observer, Bessel recommends calling the bars A and B; A should be brought between the micrometers, then B, B again, and then A. These four measures he calls one comparison. The observer then should station himself on the other side of the comparateur, and make a second comparison. Bessel made a number of comparisons of two bars in a cellar, where the change of temperature was very small.

The means of four comparisons, two before and two after, the bars were turned, differed from the mean of fourteen sets of 1 inch from comparisons by the following fractions of a line:—

— 0.00010  
— 0.00010  
— 0.00003  
+ 0.00013  
— 0.00001  
+ 0.00010  
+ 0.00002  
— 0.00002  
— 0.00011  
— 0.00018  
+ 0.00011  
+ 0.00009  
+ 0.00007  
0.00000

To make the axes of the bars coincident with the common axes of the steel cylinders a ring carrying a föhlhebel (lever of contact) can be fastened on the end of either cylinder. Bring the föhlhebel in contact with that portion of the end of the bar which is cylindrical, and turn the cylinders round its axis. If the long arm of the föhlhebel remains pointing to the same division of the arc, along which it moves, the end of the bar is strictly centred, if not the long end of the lever will move on the graduated arc. A Prize Medal was awarded to Mr. Baumann.

SIMMS (No. 741, pp. 475-477,) exhibits the three standard yards, prepared for Her Majesty's Commissioners, for the restoration of the standard of length, with two methods of supporting them; one by Professor Miller, consisting of a system of levers, by which an equal degree of pressure is sustained upon eight equidistant points of the bar; the second by the Rev. R. Sheepshanks, by floating the bar in mercury, which is therefore equally

\* For a complete description of this instrument, see Bessel's "Darstellung der Untersuchungen und Massregeln, &c.," Berlin, 1839.

supported at every point throughout its length; the bar is covered with a coating of gold-beater's skin to defend it from attack by the mercury. It is probable that the former is the better method, as the latter, though good in theory, is probably not good in practice, from the fact that iron rusts easily in mercury, and copper and its alloys combine easily with it.

Mr. Simms also exhibits two standard scales, which have been used for the formation of many scales now in use. They were made by the exhibitor, whose property they are. The tubular scale is No. 3 of Mr. Bailey's Report on Standard Measures.\*

#### *Dividing Machines.*

ACKLAND (No. 368, p. 450) has exhibited a machine for dividing hydrometers and other variable scales, with accuracy. The instrument is furnished with a mounted head, screw, and suitable cutting apparatus.

The usual means of graduating hydrometers is by determining three points by means of three different fluids, whose specific gravities are known, and dividing the intervals between these points into equal parts. This method is evidently defective, as the divisions, instead of being equal, increase, in a given ratio from below upwards.

The plan adopted by Mr. Ackland may be divided into three processes:—

1st. The ascertaining the exact position of three or more points of the scale, according as the stem of the hydrometer is more or less cylindrical.

2ndly. The dividing with great accuracy a scale on box-wood, to show the specific gravities required to be indicated by the hydrometer, and to be used by the instrument for the purpose of measuring and correctly marking the distance of one division from another on the paper scale with true mathematical certainty.

3rdly. The making a reduced copy of the box-wood scale, so as to form a scale, the points of which shall correspond with the distance between the ascertained points of the hydrometer bulb. The scale so formed on paper is the scale for the hydrometer. For example, suppose it be required for a hydrometer to show specific gravities from 1.000 to 0.700; to show this a bulb is chosen with a stem as uniform as possible, and three points, viz., .700, .850, and 1.000, are ascertained as follows:—

Let  $a, b, c$  be the degrees required. Suppose  $m$  be the point on the stem whereon it is required to mark the highest specific gravity, viz., 1.000 =  $a$ . To find this point, the instrument is loaded until it floats in distilled water at the temperature 62° Fahr., at the point  $m$ ; let the weight of the instrument then be  $x$ .

To find .850 =  $b$ .

Load the instrument until it weighs  $\frac{ax}{b}$ , where it floats in distilled water, mark the tube at  $a$ .

To find .700 =  $c$

Load the instrument until it weighs  $\frac{ax}{c}$ , where it floats in distilled water, mark the tube at  $a$ .

Finally, before sealing the instrument, make it weigh  $ax$ ; then  $m, n, o$  will respectively represent the specific gravities required. By this plan, which was suggested to Mr. Ackland by Dr. Clark, of Aberdeen, the correct position on the stem of the three specific gravities is obtained; the next and most important operation is the subdivision of these spaces, so that each division shall be in its true position. This is done by copying a calculated scale by aid of the machine, the construction of which is such that a proportionate scale of any length less than the original can very readily be produced.

The scale is determined by forming a table of the reciprocal of the specific gravities, and taking the differences between them; in use the micrometer head is successively advanced, and each division is cut with accuracy and with great rapidity.

Most of the scales of the hydrometers exhibited have

been graduated in the usual way, and are therefore inaccurate; those exhibited by Griffin (No. 467), were performed by this machine, which Mr. Ackland has the merit of inventing. He is the first in England who has carried into active practice a correct mode of subdividing glass vessels for gases and liquids by the aid of a machine.

The cutter is made to cut, and cuts a division. The detent, apparently, is then brought back to the common centre of the helix screw, either by lifting, unclamping, and re-clamping, or in some equivalent way, and runs its course again to bring the cutter ready for another cut, and so on. There is also a second novelty, viz., a neat little contrivance to make every fifth division longer than the rest by means of a wheel which advances one step at each division or movement of the cutter frame. A point, let drop to touch its circumference, determines, by the depth to which it descends, the length of the cut; but at every fifth step the wheel has a notch into which the point descends, allowing the cutter to make a longer stroke—longer by the depth of the notch.

A Prize Medal was awarded to Mr. Ackland.

PERREAUX (France, No. 369) has exhibited a straight line divider. This is a beautifully-contrived divider on Ramsden's principle, with a long fine steel screw. The novelties are, first, the wheel at the screw head, which is divided into 400 parts, and has cut upon its circumference (which is made broad), a helix screw, in the thread of which runs a detent carried along by the run of the thread till it meets a stop clamped on the helix at a definite point. This arrests the screw, at this point of the motion. A Prize Medal was awarded to M. Perreaux.

FROMENT (France, No. 1609, p. 1254.) exhibits a divided metre, the divisions on which are beautifully distinct, and as far as could be ascertained, very exact. It is believed that the divisions were cut by M. Froment's dividing engine, which he has constructed for dividing astronomical and geodetical instruments. M. Froment has also constructed a screw more than a metre in length, for the purpose of dividing lines quickly, and it is understood that in so doing electricity is made use of in connection with the movements of the screw and machine.

A Council Medal was awarded to M. Froment.

THE CONSERVATOIRE DES ARTS ET MÉTIERS (France, No. 1568, pp. 1251, 1252.) exhibits a brass metre by Gambey, decimally divided. Also a fine platinum metre, which is described as the "second type of the Collection of Weights and Measures of the Conservatoire des Arts et Métiers," executed by M. Brannen, and compared by M. Silbermann, and is stated to be a copy of the ancient platinum metre of the same collection, an immediate derivative of the prototype in the archives of France, and to be longer than that, of which it is an immediate copy, by 0.000019 millimetre.

It is properly speaking a "metre à bouts," and is converted into one "à traits" by attaching to each of its extremities a supplementary piece of platina, separated from the bar by a very thin lamina of gold, which appears as a fine line of gold at the junction. It is supported on a bed of bronze, to which it is attached firmly and by accurate adjustment at one end, whilst the other is left free to slide by expansion, thus converting the whole system into a Borda's pyrometer, the amount of relative expansion being read upon a scale, the value of whose points has been derived from experiment by immersion in melting ice and boiling water.

The Conservatoire des Arts et Métiers also exhibits a standard kilogramme and litre; a series of French coins of legal currency; and a collection of wood measuring rods, both in single lengths, and in more or less numerous joints; also measuring chains, and a series of measures of capacity of the following values (in litres), viz.:

20, 10, 2, 1,  $\frac{1}{2}$ ,  $\frac{1}{4}$ ,  $\frac{1}{8}$ ,  $\frac{1}{16}$ ,  $\frac{1}{32}$ ,  $\frac{1}{64}$ ,  $\frac{1}{128}$ , in brass, with ground rims and sliding glasses to each.

#### *Balances.*

The Exhibition contains balances of all sizes, from Mr. Fox's balance, intended to carry extremely small weights, up to the balances of L. Oertling and the American balance, both of which are capable of carrying

\* See the 'Transactions of the Royal Astronomical Society.'

56 lbs. in each pan. Many of them have probably never been surpassed, in the construction of the beam, knife-edges, planes opposed to them, permanence of the adjustments and beauty of workmanship; yet in all, the position of the beam, when loaded with the weights to be compared, is shown by a long index nearly in contact with a graduated arc, although for several years other and greatly superior methods of determining the position of the beam have been in use, such as by a graduated arc attached to one end of the beam, and viewed through a compound microscope having a horizontal wire in the focus of the eye-glass, or by a mirror attached to the beam, in which the reflected image of a scale is viewed through a telescope.

In the balances exhibited the beam and pans are suspended on knife-edges, more or less in length, with the single exception of Mr. Fox's balance, in which the beam has pivots, the conical ends of which play in hollow agate cones of larger angle.

There is no example of the balances constructed under the direction of Gauss and Weber, and described in the "Göttingen Transactions," in which the beam is suspended by two watch-springs, and each pan by a single watch-spring; nor of either of Steinhil's balances, in which the beam and pans are suspended by wires or silk ribbons; nor of the balances first (Professor Miller believes) invented by Steinhil and used by Kupffer in comparing the Russian standard of weights, in which the beam carries two small steel spheres in the middle, resting upon a steel plane, and a sphere at either end, upon which rest the plane or slightly concave spherical surfaces of the plates from which the scale-pans are suspended.\*

There are a variety of contrivances for checking the oscillation of the beam and pans when in action: none of them can compare in simplicity and efficiency with the apparatus invented by Wollaston, and used by the late T. C. Robinson, Barrow, Dover, and by most of the English makers of balances, and also by Nissen, of Copenhagen, the only foreign maker who appears to have made use of it.

In nearly, perhaps in every instance, when the divisions of the scale, to which the index of the balance points, were numbered; the division to which the index points when the beam is horizontal is marked zero, and the scale numbered 1, 2, 3, &c., to the right and left. This method is most inconvenient, and frequently leads to error. The number of the divisions ought to run all the same way, and need not begin with zero, it being far better to number that division to which the index points, when the beam is horizontal, 10, 20, or some multiple of 10, for the purpose of avoiding the trouble, perplexity, and liability to error, attendant upon the necessity of noting numbers, in addition to whether the numbers are positive or negative. This remark is of general application to all instruments to which scales are affixed.

L. OERTLING (No. 334, p. 446) exhibits a large balance having a beam 3 feet in length, coated with platinum,† and capable of carrying 56 lbs. (equal to 25·4 kilogrammes) in each pan. The beam, a pierced rhomb, is constructed so as to give great strength in proportion to its weight. Any tendency to lateral yielding is counteracted by resting the beam with edge 1 on a steel surface.

The whole length of the middle knife-edge rests upon a plane surface of steel: the three knife-edges are long. Plane surfaces of steel, from which the scale-pans are suspended, rest upon the extreme knife-edges. When not in action the beam and the steel planes from which the scale-pans hang, are supported, so as not to be in contact with each other. The frame for supporting the beam and pans is extremely well contrived; so also is the mechanism for lifting it.

He exhibits also a balance capable of carrying one kilogramme in each pan. The beam of this balance, which is 16 inches long, is coated with palladium;‡ the three

knife-edges, as well as the plane upon which the middle knife-edge rests, and the planes from which the pans are suspended, are of agate, so that the whole instrument is unaffected by acid vapours. The beam is graduated, and small differences of weight are determined by a small weight that can be placed upon parts of the graduated beam. The beam and pans are supported, excepting when in action. The adjustments of the knife-edges, in the direction of the length of the beam, are as few as possible to be very permanent. The knife-edges are not capable of any adjustment after leaving the artist's hands in a direction perpendicular to the length of the beam. As far as the beam and knife-edges are concerned, a better balance has probably never been constructed. He exhibits also a smaller balance: the beam is 14 inches long, similar to the former in construction, and capable of carrying about 1,000 grains. A Council Medal was awarded to Mr. Oertling.

DOVER (No. 344, p. 449) exhibits a balance, which in construction is similar to the balances constructed by the late T. C. Robinson, and, in execution, fully equal to the balances made by that most excellent artist. The beam is 10½ inches long, and is capable of carrying about 2,000 grammes in each pan.\* The three knife-edges are of steel, the planes opposed to them being made of agate. The final adjustments, both in the direction of the length of the beam and in a direction perpendicular to it, are effected by a cut at each end of the beam making an angle of about 45° with the axis of the beam, which may be widened by means of a screw. This is an excellent mode of adjustment, succeeding perfectly, and proved to be very permanent when confined to extremely narrow limits. If these limits be exceeded, as they sometimes are in unskilful hands, the end of the beam is cracked and destroyed.

Mr. Dover has substituted chains with long links for silk threads, for suspending the pans, and has added an ingenious contrivance for supporting glass tubes in weighing.

A Prize Medal was awarded to Mr. Dover.

FOX (No. 377, p. 451) exhibits a balance for extremely small weights, which has instead of a knife-edge at the middle, an axle ending in conical points, which points play in conical holes (the angle of the cone in the holes is, of course, greater than the angle of the cone of the pivots). The attraction of a magnet brings the beam exactly to zero before weighing. In order to overcome the friction, of which much is introduced by the construction of the balance, there is an instrument for rasping on the case.

MARRIOTT (No. 341, p. 419) exhibits a chemical balance, the beam of which is made of a wide bit of wood (fir), with interstices cut out so as to leave a strongly framed network. The knife-edges do not appear to admit of any adjustment. The scale-pans are suspended from double hooks of wire hanging on the end of the knife-edges. This instrument is a curiosity: it is stated by the maker to be sensible to the 100th of a grain. It is a good example of a make-shift for a balance, when at a distance from good workmen.

DE GRAVE, SHORT, and FANNER (No. 333, p. 446,) exhibit two assay-balances, apparently of very good workmanship, but not adjusted,† and a large number of commercial balances of various kinds, weights, and measures of capacity and length.

BACHE (United States, No. 395A, p. 1462).—Large balance, capable of carrying 56 lbs. (equal to 25·4 kilogrammes) in each pan. The knife-edges are square bars of steel. Each bar is fitted into a socket attached to the beam, having a rectangular notch, so that any one of the four edges of the bar may be used as a knife-edge.‡ The

this successful application, that the same process is applicable to graduated instruments.

\* A similar balance, finished by Mr. Dover, was used repeatedly by Professor Miller to weigh 5,760 grains, and was not in the slightest degree injured.

† The centre of gravity is too high to admit of using them.

‡ In the event of one of the edges being damaged this arrangement is of great service.

\* See Kupffer's work on the "Comparison of Standards" for a description of this balance.

† These beams were coated by T. H. Henry, Esq., F.R.S., by a peculiar process, in which the electric current was employed in depositing these metals. It would seem, from

socket, in which one of the extreme knife-edges is fixed, moves in a slit in the direction of the length of the beam, and is adjusted in that direction by means of two screws.

A smaller balance is exhibited, of almost exactly the same construction as the preceding; it is capable (probably) of carrying a kilogramme in each pan. A Prize Medal was awarded to Mr. Bache.

DELEUIL (France, No. 160, p. 1178) exhibits a large balance, capable of carrying two kilogrammes in each pan. The middle knife-edge rests upon a plane surface of steel. The pans are suspended from plane surfaces of steel, which rest upon the extreme knife-edge. Screw adjustments appear to be avoided, in order to secure invariability in the positions of the knife-edges. The cast-iron base of the balance has holes under the extreme knife-edges, for suspending large globes of glass for weighing gases, in an enclosed space beneath the base of the balance. Both the construction and workmanship of this balance appear to be extremely good.

A chemical balance, by the same exhibitor, capable of carrying 300 grammes in each pan. The pans are of platinum, suspended by silver wires.

Another chemical balance, capable of carrying 200 grammes in each pan; the pans are of platinum.

In these two balances the middle knife-edge rests upon a plane surface of steel. The pans are suspended from slightly curved steel hooks.

Balances of this construction, though considerably inferior to that in which the pans are suspended from plane surfaces, are simple, not easily deranged, and accurate enough for all the ordinary purposes of chemistry, for which they are expressly constructed.

An assay-balance, of the ordinary construction and excellent workmanship, is also from the same exhibitor.

A Council Medal was awarded to M. Deleuil.

COLLOT, BROTHERS (France, No. 1155, p. 1233) exhibit a large balance, capable of carrying two kilogrammes in each pan. In its construction and excellence of execution, it very closely resembles the large balance of M. Deleuil.

An assay-balance of the ordinary construction is also exhibited by Messrs. Collot.

A Prize Medal was awarded to Messrs. Collot.

BERANGER (France, No. 761, pp. 1216, 1217) exhibits a balance to be placed upon a counter, with platforms for holding the substance to be weighed, and the weights. With fifty kilogrammes in each pan, the addition of one gramme to the weights in either pan causes the index to move through about a quarter of an inch. When tried with twenty kilogrammes in each pan it was found to turn very sensibly on placing half a gramme in one of the pans.

M. Béranger also exhibits a steelyard in which the weight is moved along the arm by a screw of the length of the long arm, and parallel to it, having a head of about 4 inches diameter, divided into 100 parts. This steelyard is sensible to 100 grammes, with 1,000 kilogrammes suspended from the short arm.

Also, *bascule en l'air*, a double steelyard. The end of the short arm of a steelyard is connected by a link with the extremity of a lever, and at a distance from the fulcrum of the lever equal to a small fraction of its length is a knife-edge, from which the substance to be weighed is suspended. One of these, capable of weighing 1,000 kilogrammes, costs 260 francs.

M. Béranger exhibits a model of a machine for determining the pressure exerted by each wheel of a locomotive.

Also, a *peso-compteur*, a weighing-machine, which registers on a sheet of paper the weight of every article weighed. Besides these there are a great many commercial balances, all of which are most ingeniously contrived, extremely well made, very accurate, and considering the workmanship, and the number of adjustments to be attended to, very cheap. Although the Jury considered them well deserving such reward, no Medal was voted to M. Béranger, on account of these being commercial balances, and as such thought by the Jury to belong to instruments for direct use, rather than to philosophical instruments: they have, however, received a prize in Class V.

SACRÉ (Belgium, No. 504, p. 1167,) exhibits a large balance, capable of carrying two kilogrammes in each pan. The manner of fixing the extreme knife-edges to the beam is different from that usually adopted, in which the under horizontal surface of the knife-edge is in juxtaposition with the horizontal surface of the beam, widened at that particular part, and firmly fixed to it by one or more screws. In M. Sacré's balance, on the contrary, the ends of the beam terminate in vertical plane surfaces, to which are attached, by screws, vertical plates of steel, terminating above in knife-edges. The pans are suspended in such manner, that their swinging in any direction has no tendency to twist the beam of the balance.

This instrument is remarkable for the extreme beauty of its workmanship.

M. Sacré also exhibits an assay-balance, in which, contrary to the usual construction, the pans are suspended from plane surfaces of steel which rest upon long knife-edges, and are supported independently of the beam when the balance is not in action: it is therefore not only more accurate than ordinary assay-balances, but is enabled to carry 20 grammes in each pan without injury. The work is extremely good.

In assay-balances, as usually constructed, the pans are suspended from hooks, which themselves rest on hooks worked to a fine edge, attached to the ends of the beam, and are not calculated to carry a weight of more than two grammes.

A Prize Medal was awarded to M. Sacré.

A. OERTLING (Prussia, No. 87, p. 1053) exhibits a balance of very beautiful workmanship, capable of carrying a kilogramme in each pan.

The knife-edges are let into dove-tailed notches in the beam.\* The adjustment of the distance of the extreme knife-edge from the middle knife-edge is effected by means of a vertical cut in the metal of the beam, which may be slightly widened or contracted by screws. The agates which rest upon the extreme knife-edges, and from which the pans are suspended, are not plane, but have an obtuse re-entering angle, into which the less obtuse angle of the knife-edge enters, and are not suspended independently of the beam when the balance is not in action.† Two thermometers are placed with the bulbs as high as the beam; but it probably would have been better if the bulbs had been placed a little above the scale-pans, for the temperature of the air immediately surrounding the object to be weighed often differs sensibly from that of the air in the upper part of the balance-case.

Oertling has also two smaller balances, of similar construction, capable of carrying 100 grammes in each pan. A Prize Medal was awarded to Mr. Oertling.

REIMANN (Prussia, No. 86, p. 1053). Balance, capable of carrying one kilogramme in each pan. The knife-edges are opposed to agate planes. The adjustment of the position of the knife-edges is effected by means of an oblique cut at each end of the beam, the breadth of which may either be increased or diminished by screws.‡ This is the only balance in the Exhibition in which a circular level has been adopted. The Jury considered it worthy of Honourable Mention.

HOFFMANN and EBERHARDT (Prussia, No. 88, p. 1053) have exhibited balances for apothecaries: they seem well suited to the purpose they are intended to serve.

LUHME, J. F., and Co. (Prussia, No. 83, p. 1053) exhibit chemical balances. One of them is capable of carrying one kilogramme in each pan; another of carrying 100 grammes in each pan; a third 50 grammes in each pan; and a fourth 25 grammes in each pan.

A Prize Medal was awarded to Messrs. Luhme.

BATKA (Austria, No. 135, p. 1014) exhibits a very small balance by Kuseche, of Vienna, contained in a platinum

\* It is doubtful whether this mode of attaching the knife-edge is quite as good as when the beam is made wider at the extremities and the middle, and the whole length of the knife-edge rests upon it.

† The form of the agates seems to be objectionable.

‡ In the present case, too much reliance seems to have been placed on this mode of adjustment; for one of the cuts has been widened by screwing till a crack in the beam has begun to form.

blowpipe apparatus. It is very well made, and the Jury deemed it worthy of Honourable Mention.

**DOLBERG** (Mecklenburg-Schwerin). Balance, to carry one kilogramme in each pan. This balance is in many respects very well constructed: but the middle knife-edge is supported by two agate planes, and the bearings of the knife-edge on the planes are rather short, both of which circumstances are defects. The oscillation of the pans is checked by hair-brushes, which on turning a handle ascend till the ends of the brushes touch the under-sides of the pan: in this arrangement there is reason to apprehend that loose hairs might attach themselves to the under-sides of the pans, and so lead to an error in the weighing.\* The pans are suspended from plates of steel, having plane surfaces, which rest upon the extreme knife-edges.

A Prize Medal was awarded to Mr. Dolberg.

**BECKER** (Netherlands, No. 83, p. 1147). Balance, capable of carrying one kilogramme in each pan. The beam is a single bar, the middle knife-edge being supported on two agate planes.† The contrivance for lifting the pans and beam, when not in action is ingenious, inasmuch as the motion is slow at the time the beam is deposited on the middle support, and the agate planes from which the pans hang on the knife-edges: but it is unsteady in a lateral direction. There is also reason to apprehend the extreme knife-edges would not touch the agate planes in the same parts in successive weighings. The method of attaching the pans to the brass rods by which they are suspended, in such a manner as effectually to guard against upsetting the pans wherever the weight may be deposited, is extremely simple and ingenious. The Jury considered it worthy of Honourable Mention.

**NISSEN** (Denmark, No. 20, p. 1356). A large balance to carry 10 lbs. (4.54 kilogrammes): the middle knife-edge is cut away in the middle, so that the bearings of the edge on the middle plate are too short. The pans are suspended from plates having concave surfaces, which form of plate is objectionable. They are not supported independently of the beam, when the balance is not in action.

The eccentric motion for putting the balance in action had been injured, so that it could not be tried.

A small balance exhibited by Nissen, capable of carrying more than 100 grammes. The middle knife-edge in this, also, is cut away, so that the ends only touch the plane surface on which it rests. The balance in other respects resembles Robinson's balances, except that the middle knife-edge rests upon two planes, and that the plane surfaces are of steel instead of agate. It is furnished with Wollaston's contrivance for checking the oscillation of the pans and beam.

The same exhibitor has also a small assay-balance.

The Jury considered Mr. Nissen as deserving Honourable Mention.

**LITTMAN** (Sweden, No. 15, p. 1350). In this balance the index is at one end of the beam. In addition to this index there is another pointing upwards, the end of which is viewed through a compound microscope, having a divided scale or glass in the focus of the eye-piece. This contrivance for reading off the extreme portions of the balance during its oscillation is far inferior to a graduated scale, attached to the beam of the balance, observed with a compound microscope having a single wire in the focus of the eye-piece. It also adds greatly to the bulk of the balance-case. The Jury considered this balance deserving Honourable Mention.

**VINEAU** (Sweden and Norway, No. 14, p. 1350) exhibits a chemist's balance, which the Jury considered worthy of Honourable Mention, it being well adapted for the purposes it has to perform.

#### *Coin-Weighing Machines.*

We will now turn our attention to another class of balance, recently introduced, viz., coin-weighing machines. Of these there are three in the Exhibition—one exhibited

by W. COTTON, Esq., late Governor of the Bank of England; a second by Captain SMITH; and a third made by DELEUIL (France, No. 160, pp. 1178—1180); this last instrument was designed by Baron SEGUIER.

Before proceeding to the particulars of these beautiful instruments, it may be well for a short time to dwell upon the want which has called them into existence, as kindly explained by William Miller, Esq., of the Bank of England. All sovereigns brought into the Bank of England by the public are weighed singly, and this is found to be absolutely necessary; else the stock of sovereigns in the Bank would very soon fall below the legal current weight of 122½ grains each. The Bank, therefore, is compelled to weigh all the gold coin it receives singly, to guard against loss.

In June, 1842, the Queen's Proclamation was issued, commanding all persons to cut and deface whatever gold coin was found to be below the current weight. Before that time the light sovereigns, though they were rejected by the Bank, were accepted almost everywhere for their full value, and the public were not disposed to criticise very nicely the Bank's weighing, as the rejection of their money occasionally, when it was really of the current weight, or the issuing it to them a trifle below the weight, was of small consequence; for, though it might occasion a little trouble, it entailed no loss. But it was quite a different affair when their sovereigns were cut as well as rejected, so that they were obliged to sell them as bullion, sometimes at a loss of three-pence or four-pence a-piece; or when, as was sometimes the case, they received sovereigns at one counter of the Bank which were cut and returned to them when tendered at another. The public then, as might be expected, were very angry; but there was no help for it. The Bank had provided the best scales that could be procured: they had the most experienced weighers; they re-weighed singly every gold coin in their stock, amounting to upwards of £8,000,000, and weeded it of all the light pieces that could be detected, at a loss of between £3,500 and £4,000; but the evil remained. Sovereigns were still issued at one counter which were rejected and cut at another.

This did not arise from any fault either of the Bank or of its officers, but from the inherent difficulties in the operation of weighing so accurately as was necessary, or with the same result, in a limited time, even with the best-constructed scales. Some of the causes of error Mr. Cotton ascertained to be—differences in the weights made (notwithstanding the Mint stamp attached to them), of considerable amount in relation to the degree of correctness required; currents of air acting unequally upon the scale-pans; a constant diminution of the weight of one pan, by the act of placing and displacing the coins to be weighed, by which the equilibrium was every moment destroyed; the striking of the scale-pans upon the counter; difference in the judgment of the weighers; the short time which could be allowed for the operation; failing of the eye-sight, flagging of the attention, and sleepiness from the monotony of the employment; difference in the rate of vibration of the beams; defects of principle in the construction of the scales, to obviate which would have destroyed their simplicity and marred their general usefulness.

All these difficulties (and they were great) were overcome by Mr. Cotton's machine; and since the year 1844, out of the large number of 80,000,000 of pieces which have been weighed, not a single source of error has been made out against them. Some few sovereigns are still weighed as they are received from the public by the common scales; but such are never re-issued by the Bank until they have passed through the machines, which extract from them about two per cent. of lightness. The Bank sustains the loss upon these unavoidable errors, in preference to the loss of time, the trouble, and the vexation which the re-issue of them as they were received from the public would occasion to all parties.

We now proceed to the description of Mr. Cotton's machine.

It consists of a square brass box: on the top is placed a hopper to hold the sovereigns to be weighed. This hopper is a long trough, placed at an angle of about 45°

\* This contrivance is greatly inferior to Wollaston's for effecting the same purpose.

† This is not a good construction.

with the top of the box: it will hold about 500 sovereigns. In front of the box are two small apertures, to which are fitted two receivers, one for the sovereigns of full weight, the other for those which are light.

Inside the box, and near the upper plate, the beam or balance is placed; at one end of the beam, and above it, is poised upon a knife-edge, a small platform, which receives the sovereigns to be weighed. This platform, which, in fact, is one of the scales, is kept in its position by means of a small pendulum, on which, at about an inch below the platform, there is an oblong perforation, about half an inch in length, technically called a slot, in which a small ivory rod works freely up and down without touching the sides.

Between the slot and the platform a pair of forceps is placed. From a knife-edge at the other end of the beam a small round polished plate is suspended, to which a pendulum is fixed, and at its lower part the scale is placed to receive the weight. Above the small round plate, under the top of the box, is fixed an agate with a blunt point. When the machine is in motion the small ivory rod is depressed: this, on touching the bottom of the slot, or opening in the pendulum in which it works, brings down the beam on that side, and raises it, of course, on the other, the weight side, until the small round plate on that side touches the agate point. The beam is then in a horizontal position. As soon as this is effected the forceps catch hold of the pendulum between the platform and the slot, and hold it firmly. The balance is then in a condition to receive the sovereign, which is shifted from the bottom of the pile in the hopper, and brought by means of a slide along a channel, just large enough for a sovereign of the proper standard gold to pass, but not large enough to admit a counterfeit, and deposited upon the platform. The forceps then let go their hold, the ivory rod is gently raised, and if the sovereign happens to be light that end of the beam rises, and the other end leaves the agate point; but if the sovereign be full weight, the beam remains stationary, and the small plate on the weight end is in contact with the agate point.

When the sovereign is weighed, the operation of its removal is very ingenious, and is as follows:—Two bolts are placed at right angles to each other, and on each side of the platform or scale there is a part cut away to admit of the bolts striking so far into the area of the platform as to remove anything that would nearly fill it. These bolts are made to strike at different elevations, the lower one striking (as to time) a little before the other. If the sovereign be full weight the scale remains down, and the lower bolt knocks it off into the full-weight box. If the sovereign, on the other hand, be light, it rises up, the first bolt strikes under and misses it, and the higher bolt then strikes and knocks it off into the light box. This machine weighs about thirty-three sovereigns in one minute. The weights used are of glass, and are adjusted to within the ten-thousandth part of a grain.

It is understood that these machines, since they began to be used in 1844, have not cost £5 for repairs, and that they effect a saving in salaries alone of full £1,500 per annum, after deducting ten per cent. for the replacement of capital sunk in their establishment.

A Prize Medal was awarded to Mr. Cotton.

SMITH (India) has exhibited a coin-weighing machine, which is an exceedingly ingenious application of that of the areometer or hydrostatic balance. The counterpoise to the point weight of the scale-pan and coin is made to rise and fall in a cylinder of water, the oscillation being deadened by a circular plate forming part of the counterpoise wholly immersed in the fluid, and of such an area as to afford considerable resistance to the rising or sinking motion. By a proper adjustment of the diameter of that portion of the counterpoise which is partly beneath and partly above water, and of the length of the lever arm which carries the scale-pan, a given deviation in the weight of the coin one way or other from its legal weight may be made to correspond with a given depression or elevation of the counterpoise, and therefore of the scale-pan, below or above a certain medium or zero position, the scale resting at a level, corresponding to the amount of excess or defect of the coin above or below the standard.

At levels corresponding to half grains of difference of weight, shelves are placed which receive the coins from the scale-pan, according as, on arriving at its point of equilibrium, it happens to be opposite to the interval between either shelf and the next above it; and once thrown upon that shelf, it glides down and finds its way into a receptacle corresponding by an appropriate passage. Thus the coins enter twelve panels, differing each by twelve grains of weight.

To throw the coin off the scale upon its proper shelf, the scale-pan is peculiarly constructed of wire, horizontally laid, so as to allow a scraper, also of wire, vertically arranged, to pass between and beside the frame-work of the pan, which, being pushed along at the end of each weighing, the coin is forced by it off the pan upon the shelf. The pan-frame, thus lightened, rises to the proper position for receiving another coin, which is placed on it by a feeding-pipe in the manner usual in coining processes.

Any number of small weighing-machines may be mounted side by side, so as to occupy a very moderate compass, and may be worked simultaneously by a common feeding and a common discharging movement; and all may be made to discharge their contents on the same shelves conducting to common receptacles.\* A Prize Medal was awarded to Captain Smith.

DELEUIL (France, No. 150, pp. 1178—1180) exhibits a beautiful coin-weighing machine, invented by Baron Segnier, Membre de l'Académie des Sciences, differing, however, from those above described in its mechanical arrangements, and in some particulars of construction which are necessary to its performance of the additional operation required by the French Bank.

In the Bank of France each piece of money is weighed in a small balance, especially constructed for the purpose, by men charged with this particular duty. The beautiful coin-weighing machine in question is designed to supersede this work by mechanical means. In its working it exhibits quickness and regularity in performing the operation of distributing the pieces into three classes, those which are heavy, those which are of exact weight, and those which are light.

The instrument is distinguished in its operations from Mr. Cotton's, by thus distributing the pieces into three classes instead of two, as in Mr. Cotton's, the three being necessary in the Bank of France, though not required in England.

The right to this elegant invention not being secured by a patent, its internal construction could not be examined; but so far as could be judged from working it, as exhibited, the principle seems to be the same as in the able the declination of the index of the balance, or light steel rod, to the right or left of the vertical, according to the excess of weight in either pan, to give motion to one or other of two light brass plates in the act of raising the balance. The force so applied being, not the mere difference of weights between the scales, but an external power applied through this medium; the motion thus given to the brass plate being conveyed downwards by an appropriate train of mechanism might easily be applied to an interposed obstacle or otherwise. The coin, on its delivery from the scale, is diverted from that passage which it would have followed had the index remained vertical, into one of two other channels according to the inclination of the index.

The machine is fed by a hopper, the coin being thrown promiscuously in. To prevent its jamming, and refusing to pass, it is constantly stirred from below upwards by a wheel set round with steel pins so as to disturb the self-arrangement of the coins in the hopper, and let them fall over one by one into the feeding-trough. It is understood that about fifty coins could be weighed per minute by a double machine, such as that exhibited. The working appeared to be not quite continuous, but in all other respects perfectly satisfactory, the interruption

\* A full description of this ingenious mechanism, which was contrived and executed for the Madras mint under Captain Smith's direction, will be found in the "Professional Papers of the Madras Engineers," vol. ii.

to the regular delivery of the coins being little more than momentary.

It will be understood that, for the reason above assigned, this account of its operation is merely conjectural. Sir John Herschel remarks that it would be easy to devise a machine for a similar purpose, founded on the principles, first, of preventing the descent of either scale, unless the excess of weight in it surpassed the legal "remedy," and allowance for wear and original error, which might be done, by giving each end of the beam a support from below equal to the remedy, but rising only on its descent; and, secondly, by presenting in the closest proximity to the under-side of the beam, but not in actual contact, the extremity of a conducting rod of copper, completing a galvanic circuit through the beam and its central steel knife-edge resting on a steel plane, and thus animating one or other of two electro-magnets, which by its attraction on a soft iron bar should shift either the point of delivering or the point of reception of the descending coins, on their egress from the scale. The circuit being completed, the right-hand conductor would thus deviate the coins into the receptacle for heavy, and the conductor on the left into that for light coins, while a state of rest of the beam, corresponding to any excess *within the remedy*, either way, would cause no deviation, but allow the coins to fall straight into the middle receptacle. This description might enable any mechanist to construct such a machine, probably at small cost, and without infringing any patent right.

It is highly satisfactory to find an instrument of such high importance as the balance so well represented in the Exhibition; and when it is considered, in order to have a balance as perfect as possible, how very many circumstances are to be attended to, it must be deemed highly honourable to the exhibitors of good balances to have produced instruments standing the test of the rigorous examination to which they have been subjected. We observe, however, in the Exhibition, no self-weighting balances for small weights (up to 1,000 grains), on the principle of Mariott's spring-balance for large ones, or on that of the simple extension of a long spiral spring, which is a very convenient form of instrument when great accuracy is of less consequence than expedition.

#### *Air-Pumps.*

Most of the important facts which we know relative to the properties of air may be said to have been elicited by the employment of the air-pump. It is satisfactory to find in the Exhibition contains instrument of a new and improved construction; but it is matter of regret that so small a number of manufacturers have contributed.

The air-pumps most commonly used are made either with brass stop-cocks, or with valves of oiled silk or leather. The former, when properly constructed, and new, generally act well, by exhausting the air thoroughly; but after having been in use for some time, they become less accurate than those furnished with valves, after an equal amount of wear. But the valves themselves are also imperfect, owing to the pressure of the external air on that within the piston preventing the latter from rising when the air is almost exhausted. Attempts to overcome this difficulty have been made in the pumps exhibited, some of which are very superior in their action, and have probably never been surpassed.

The exhibitor of the best air-pump is NEWMAN (No. 674, p. 468<sup>a</sup>). This has a ground-glass plate, to avoid injury from sulphuric acid. It has two pumps with metal valves: on one of these are two barrels, open at the top to the atmosphere, as in the common table air pump; this arrangement exhausts the receiver quickly, but on account of the nature of the valves, not beyond  $\frac{1}{4}$  inch or  $\frac{1}{5}$  inch of mercurial pressure. The other pump has a single barrel, with an oil cistern at the upper part, the air being lifted through a valve at the bottom of this cistern. If anything re-enters the barrel it can only be oil, which is brought out with the air at the next up-stroke of the piston. The piston has a metal valve; but the opening of this valve is not necessary to the continuation of the exhaustion, as the piston at its lowest point passes below the aperture leading to the receiver. This construction

of air-pump exhausts more thoroughly than any yet known.

In the experiments which were tried, the reading of the barometer at the time being 30.08 inches, the gauge of the air-pump stood at 30.06 inches. A Council Medal was awarded to Mr. Newman for this air-pump.

WATKINS and HILL (No. 659, p. 466<sup>a</sup>) exhibit a new double-barrelled air-pump, on a plan suggested by Mr. Grove. It has oiled-silk valves, and is so constructed as to leave the least possible residue of air in the barrel, after each stroke of the piston. The piston is solid, without a valve, and the shape of its lower part is an obtuse cone: part of this cone rises at the top of each stroke above the aperture leading to the receiver, and the air which has entered the barrel is, by the down stroke, forced through a valve at the apex of the hollow cone terminating the lower end of the barrel, to which the lower end of the piston fits very accurately. The piston-rods pass through air-tight leather collars in the tops of the barrels. This pump exhausted the air till the elastic force was only 0.05 inch of mercury. A Prize Medal was voted to Messrs. Watkins and Hill.

KNIGHT and SONS (No. 453, p. 462) exhibit an air-pump on Siemen's patent. It consists of two cylinders, of different diameters, the smaller one placed below the larger, and separated from it by a plate forming the bottom of the upper and the top of the lower cylinder. A piston-rod, common to both cylinders, passes through a stuffing-box in the plate, attached to which are two valved pistons, working in their respective cylinders. The advantage of this construction is, that the pressure of the external air on the oiled-silk valve of the larger cylinder is taken off by the vacuum formed in the smaller one, and in consequence no greater resistance is offered by the valve than that arising from its adhesion and tension. The exhaustion of this pump is very rapid, and in the trial amounted to 0.21 inch of mercury.

VARLEY and SONS (No. 257, p. 436) exhibit an air-pump upon a new construction. It is worked by a continuous rotatory motion of the handle, slide-valves being used to open and close the communication. On the piston arriving at one end to expel air from the barrel, it is followed by rarefied air from the receiver; the slide-valve closes upon the receiver, and connects the two sides of the piston; the residual air expands into the larger space, becomes equally rarefied, and the subsequent motion of the valve separates these spaces, and connects the receiver with the closed end; the piston then returns to exhaust air into this end of the barrel and to expel it from the other, and thus continuous exhaustion is kept up; for, how rare soever the air becomes, it keeps flowing after the piston continually. The barrel is twice filled for every entire revolution of the handle. This pump has a single barrel with double action: it exhausts quickly, and the exhaustion was found to be 0.05 inch for a moment, but could not be maintained.

Varley and Sons also exhibit a second air-pump, smaller than the former: it has a double-acting barrel. The piston is worked by means of a crank and continuous circular motion of the handle.

HEYWOOD (No. 404a, p. 453). A rotary table air-pump, with self-opening valve worked by a crank motion. It acts with singular smoothness and ease.

G. GERTY (No. 407, p. 454) exhibits an air pump of the common table form. It gave an exhaustion of 0.3 inch of mercury, which is considerable for this kind of air-pump.

LADD (No. 291A, p. 440) exhibits an air-pump, which is single-barrelled and of a cheap construction, without any other claim to notice.

YEATES (No. 332, p. 446) exhibits a double-acting air-pump of a cheap construction, which appears to be good for its price. Its valves are of oiled silk. The communication is in the middle of the barrel, a valve being placed there and at each end. Honourable Mention was awarded to Mr. Yeates.

BRYAN (No. 408, p. 454) has exhibited a double-action air-pump, constructed without valves, and having a rotatory motion. The pump consists of a barrel, to which two smaller ones are attached on either side. In the

large or prime barrel is a solid piston, which may be made to rise and fall at pleasure, and is attached to a piston-rod; in the centre of the secondary barrels are also small pistons, whose movements are simultaneous. Each rise and fall of the large piston is designed to draw off from the receiver 53 cubic inches of air, simply by its own elasticity. The double action, combined with the rotatory motion, has been introduced with a view to economise both time and labour, and the absence of the valves, to avoid the limitation of exhaustion attendant upon their use. This pump was not tried, in consequence of no one being in attendance on the Jury to explain its action, &c.

BURTON (France, No. 1113, pp. 12, 31) exhibits a double-barrelled air-pump. It has, instead of valves, a glass plate sliding over apertures communicating with the receiver and the pumps. The motion of this glass plate is produced by the mechanism which works the pump; it is very ingenious in its construction. The approximate exhaustion is first made by the ordinary alternate action of the barrels. The system of communication is then changed by shifting round the glass plate, which serves as a valve during one-fourth of a revolution, when the rarefied air is condensed in one barrel and sucked into the other, whence it is ultimately ejected through a valve of oiled silk very close to the piston. On account of the distance between the pumps and the glass plate, however small the pipe of communication, the exhaustion must be imperfect. The syphon gauge attached to the instrument indicated an elastic force of only one millimetre of a column of mercury; but a bubble of air was seen at the top of the mercury, proving its indication to be erroneous.

DELEUIL (France, No. 109, pp. 1178, 1179, 1180). This exhibitor has a double-glass barrelled air-pump, on M. Habinet's principle, the valves being opened by means of wires passing through the pistons. The opening of the valves is by this means rendered independent of the elastic force of the air remaining in the receiver. The degree of exhaustion which can be produced must depend on the air after the action of the piston. This appeared by the syphon gauge to be about one millimetre of mercury; but the top of the gauge could not be seen so as to ascertain whether any visible portion of air was there. In this pump, also, the vacuum is first approximately made by the alternate action of the barrels, after which one barrel exhausts the other by suction.

NISSEN (Denmark, No. 20, p. 1356) exhibits a double-acting single-barrelled air-pump, of an ingenious construction. This instrument only exhausted to 0·3 inch, as shown by the gauge, which was free from any visible speck of air. The Jury considered this pump as worthy of Honourable Mention.

#### *Optical Instruments.*

The telescope is an instrument of such high importance, that it ought to command at all times, from opticians, the incessant direction of their attention to its improvement and the bringing it to the highest possible state of perfection. In the Exhibition, if we except those affixed to astronomical instruments, there are but few telescopes. Of these the larger are for the most part good. WRAY exhibits one with discs of a solid substance, instead of flint glass, which deserves commendation, as a deviation from the beaten path, that may conduct to new and important results. There are few samples in the Exhibition of optical glass; but all are good, and give great promise of an increase in the use of large telescopes. SIMMS exhibits several object glasses made of English glass; and CHANCE contributes a noble piece of apparently pure flint glass, of no less than 29 inches in diameter. DAGUER sends some wonderfully pure glass, both crown and flint. Of lenses and prisms, there is not one British contributor; France standing alone in the exhibition of some very beautiful work, which reflects high credit upon BAYERLE and BERTAUD. Of physical optics, there is but one extensive exhibitor, viz., DUBOSCQ SOLERIL, France (No. 1197, p. 1235), who has a beautiful collection of most delicately constructed instruments, adapted for physical investigation. Of microscopes there are a good many exhibited;

among which the English microscopes are found to stand pre-eminent. Of lighthouses there are two, the one being made of glass almost colourless, and the other with that of a greenish colour. The glass of neither is pure, there being many striae, &c., which must cause much light to be scattered and consequently lost. Of spectacles and cameras we shall speak in the proper place.

#### *Telescopes.*

VARLEY and SON (No. 257, p. 436) exhibit an apparatus to be used in Gregorian telescopes, consisting of three small speculums, grouped together on one stem, and fitted into a telescope, under adjustment from the eye end, by means of which any one of the three may be used at pleasure, so that the power may be changed without losing sight of the object. Within the tube are placed two slides, one near the eye end, adjustable by a screw; the other near the object end, which may be moved to and fro. The latter carries three small speculums, of different foci, mounted on a steel axis, held in a stiff frame. At the bottom of the axis is placed a toothed wheel and rack-work. This rack is kept from moving by a long bar proceeding from the first slide, so that it cannot move with the slide on which it lies; by this arrangement, on moving the slide, the wheel upon it will roll against the rack, and so present the next speculum.

The angle at which the speculums are opposed to each other on the block determines the number of teeth, or portions of the circle required to present each speculum. The diameter of the wheel determines the distance that such portions of the wheel must traverse to put each speculum in true focus. The slide nearest to the eye end is moved by a long bar, attached to it by means of a screw, while its near end lies on the other slide, and over the loop-hole. The bar has a screw handle on the outside of the telescope, by which to pull or push the further slide, and also to clamp it fast to the near slide when in the right place. This clamping connects the two slides, and causes both to obey the adjusting screw. In order to determine the exact places at which to clamp, the bar is furnished with three notches, whose distance corresponds with the difference of foci; a tooth snaps into each notch as it arrives; the hand of the observer feels this snap, and the object reappearing at the same instant, the screw is made fast. Having brought each speculum to its right distance, its perfect position is effected without trouble. The speculum wheel has three pins; against one of these a notch in the bar is urged by a spring, which holds its corresponding speculum perfectly in place, and in addition, moves the wheel and rack a little further than the hand and bar had formerly done. This simple action separates the two hooks, and thereby detaches the apparatus from each speculum whilst it is in use, leaving it at liberty to be governed only by its pin, and the notch in the bar already mentioned; the speculum by these means is held perfectly in its place. A cylindrical cap, as a protection from the weather, is made to slide over the speculums, and affords a dark margin round the pencils of light. This contrivance has been applied to telescopes of eight inches focal length, and six inches aperture.\* The Gregorian form of telescope is the shortest, and consequently best supported on the stand; and possesses many advantages, as compared with others of equal power; from its large proportionate aperture, it gives a smaller disc to the stars, and does not require a deep eye-piece, but it is desirable to obtain power by deeper and smaller speculums.

VARLEY and SON also exhibit a portable Gregorian telescope, of two inches aperture, and six inches focus. It is mounted on a brass stand, and admits of being readily packed away in a small box. When held against a post or tree, the foot and telescope form a firm triangular bearing.

As in ordinary Gregorians, the length of telescope increases the power of the small metal reflector, so that a small portion only of an object can be seen at one time

\* This contrivance received last year (1850) the large Silver Medal from the Society of Arts.

through the central aperture, it follows that with a sufficient field of view, we cannot have as low a power as would be desirable, without increasing the central aperture and the small reflector so much as to injure the telescope for the reception of high astronomical powers. To obviate this, if possible, Varley and Son have, in the first instance, made the great speculum of the shortest eligible focus, by which means the power of the small speculum is lessened and brought nearer, the angle of view being increased in the same degree. The small speculums are mounted in tubes of any length less than double their focus. This arrangement gives a more effective dark margin around the pencils of light, and such as would require a larger disc if placed behind the speculum. Small speculums of longer focus may thus be used with no greater obstruction of light, and an equally good field retained with a lower power. The mounting the small speculums in tubes effectually secures them from injury whilst in place, and when removed, a small cup completely excludes them from the air. The arm which supports them remains in the tube, it having a concentric ring, into which the small tubes are screwed for use, and from which they are more easily detached than when affixed to separate slides in the common way.

ROSS (No. 254, pp. 435, 436) exhibits a telescope of 3 feet focal length and 2½ inches aperture, of English flint glass, which, examined on test objects at 150 yards (consisting of two black marble balls, highly polished, placed in full sunshine; a watch-dial, and small balls of white ivory on a black ground), was found to perform well, giving well-concentrated images of the artificial stars produced on the marble balls, with but a small trace of uncorrected colour.

A Council Medal was awarded to Mr. Ross for this telescope in connexion with microscopes.

CALLAGHAN (No. 268, p. 437) exhibits a telescope intended for use in deer-stalking.

SALMON (No. 266, p. 437) exhibits several day and night telescopes, intended for ships' use, which are good for their price.

RICHARDSON (No. 264, p. 437) exhibits a small reflecting telescope, of 3 feet 8 inches in length. The large reflector, made of one piece of solid crown glass, was either painted, or had paper pasted against its back, thereby giving it that tendency to change figure by heat, against which Sir John Herschel has so strongly cautioned all constructors of glass mirrors.

BOYLE (No. 392, p. 451) exhibits a reflecting telescope, intended for use without a tube.

WRAY (No. 309, pp. 442, 443) exhibits a 7-foot refracting telescope, with 4½ inches aperture. The peculiarity of this telescope is the substitution of a solid substance instead of flint glass. (See Illustrated Catalogue.)

On trial it was found to be badly achromatised. The colour above the image did not seem to be that usually called the secondary spectrum, but a remain of colour not fully compensated. The glass was neither fully corrected for sphericity nor for colour. It was observed that the object lens had rather a strong yellow tint, and was somewhat blotchy, as if the material used was not quite uniform in colour; all interior reflections were destroyed, so that it could not be suspected to be other than a single glass. As a telescope it is not very good; but, though an imperfect trial, it is yet a fair attempt to move out of the beaten track, and as a step towards the possible revival of fluid or semi-fluid object glasses, deserves commendation.

WATKINS and HILL (No. 659, p. 466\*) exhibit a telescope 3½ feet focal length, and diameter of object glass 2½ inches, furnished with a finder, vertical and horizontal rack-work motion, and eye-piece with powers to 220.

MARRATT (No. 409, p. 454) sends an achromatic telescope of 5 feet focal length; it is furnished with powers of 65, 85, 120, 200, and 280. On trial it was found to be good, and to deserve Honourable Mention.

MARRIS and SON (No. 149, pp. 428, 429) have a micro-metrical and double image telescope and "coming-up glass," for measuring distances either on land or sea.

This instrument is designed for the purpose of ascertaining the distance and dimensions of any inaccessible

object by means of simple calculation; also to determine, without calculation, the distance of any known object, by means of a set of tables adapted to the scale. It is intended to act as a micrometer for the purposes of astronomy, and as a "coming-up glass," to ascertain whether a ship be approaching to the observer or receding from him, and withal to combine simplicity of construction.

BURON (France, No. 443, p. 1199) exhibits a telescope, the object glass of which is of rock crystal, 4 feet 2 inches in diameter, and 6 feet 3 inches focal length. Attached to the telescope is a finder, which embraces a field of view from 5° to 6°, and has cross wires, which, owing to the great illumination of the field, may be seen during the darkest night, and consequently the star brought into the centre of the field. On examining this instrument it was found to be good in every respect. It is fixed upon a very steady cast-iron stand, furnished with three small castors, brought into operation by means of rack-work when necessary to remove the instrument.

The object glass of this telescope is of rock crystal, which requires great care in its preparation on account of its property of double refraction. In its working the following particulars are necessary to be attended to:—

1. The crystal must be cut perpendicular to its axis.
2. In working the axis, the spherical surface must always coincide with the axis of crystallization.
3. The curvature of their surfaces must not be made too large in the angles, as double refraction would then be visible to the eye.

M. Biot has shown that an angle of 5" must always exist, but that this is not visible to the eye.\*

The formula of Huygens has been used in working the rock-crystal object-glass; it is as follows:—Supposing that the refraction, both ordinary and extraordinary, take place in the plane of the principal section.

$$m' = \sqrt{\frac{m^2 \cdot m''^2 (1 + u^2)}{m^2 \cdot u^2 + m''^2}}$$

in which  $m'$  = The index of refraction.

$m$  = The ordinary index, or minimum.

$m''$  = The extraordinary index or maximum.

$u$  = The tangent of the angle of ordination of the luminous rays with the axis of the lens.

Thus  $m'$  is always an index of refraction, intermediate to  $m$  and  $m''$ .

M. Buron has also exhibited another telescope of about the same dimensions, which was found to be good. It is supported upon a stand, invented by the late M. Cauchy, the appearance of which is elegant, but as it compels the observer to stand during the time of observation, and as it is necessary to be moved entirely when large azimuthal angles have to be passed over, it is less convenient than the cast-iron stand before described. It is made of wood, which, though rendering it liable to be affected by variations of moisture, gives it the advantage of being lighter than one constructed of iron.

M. Buron has also exhibited telescopes of various sizes, provided with terrestrial and celestial eye-pieces, and mounted upon brass stands; also nautical and pocket telescopes. In the construction of his eye-pieces, M. Buron pays strict attention to the rules of M. Biot.

Many of the portable telescopes were tried, and their performance was found to be very good; they are remarkably cheap.

A Council Medal was awarded to M. Buron.

LEBRUN (France, No. 298, p. 1191) exhibits several achromatic telescopes of a very good kind, and which are remarkably cheap.

KINZELBACH (Wurtemberg, No. 26, p. 1115) has exhibited an achromatic telescope of about 2½ inches aperture, and 23½ inches focus, constructed on the dialytic principle, in which the correction of the dispersion of the crown lens is performed by a flint lens of only half the aperture, placed mid-way between the crown lens and the

\* See Biot, "Traité d'Astronomie Physique," vol. ii., 1844, and vol. iii., published in 1846; also "Mémoires sur les Oculaires Multipliés et Achromatiques, présentés à l'Académie des Sciences, 1843."

joint focus; a principle of compensation originating theoretically, we believe, with the late Mr. Rogers, of Leith, and carried into practice with much success by Plossal. This instrument was found to give very perfect images, with no uncorrected colour, this, together with its being the only telescope of the kind exhibited, and the construction deserving of encouragement, has induced the Jury to consider it worthy of a Prize Medal. It is mounted on a stand, which, though defective in solidity, may be used as an equatorial mounting in any latitude.

Busch (Prussia, No. 89, p. 1053) exhibits an achromatic telescope of 5 feet focal length and 48 lines aperture. On examination, this telescope was found to be pretty good. The same exhibitor has fourteen other telescopes of a small size. Honourable Mention is awarded to Mr. Busch.

### *Microscopes.*

The Exhibition is rich in its collection of microscopes of all kinds, comprising instruments varying from the simplest forms to the most elaborate. Many of the latter have never been surpassed for power, goodness of object-glass, definition, large angular aperture, beauty of workmanship, great convenience of the subsidiary parts, combined with great permanence of adjustment.

The microscope has been rendered second in importance only to the telescope by its application to physical researches. To the science of geology it has been made to display its great powers in the discovery of many strata of considerable thickness, almost entirely composed of infusorial remains, too small for the naked eye to distinguish or appreciate their exquisite beauty of form and structure. To members of the medical profession its services are indispensable; and in various ways it may become of essential use to every class of society. By knowing the microscopic appearance of different articles, a microscopist may, with ease, detect adulteration in any form, as in adulterated bread or flour for instance, the presence of any grain other than that of wheat will be readily discovered, the starch in each variety of grain being possessed of a distinctive character, and in textile fabrics the intermixture of cotton with linen can be immediately detected. But these are two isolated illustrations out of many far too numerous to be mentioned.

When Tully constructed the first achromatic object-glass in this country, in the year 1824, Dr. Goring said, "that microscopes were now placed on a level with telescopes, and, like them, must remain stationary in their construction."\* This prediction fortunately has not been verified, as the most careful examination of the instruments in the Exhibition has fully exemplified. To trace the causes of the steady and progressive improvements which have resulted in the production of microscopes of such perfection as those exhibited is most desirable. Mr. Bowerbank, who has always taken an active part in these improvements, has kindly furnished the necessary information.

About the year 1824 the first effective movement was made towards applying achromatic object-glasses to the compound microscope. In the same year the report of Selligum's microscopes was made to the Royal Academy of Science; and Amici resumed the subject after an interval of nine years. The late Mr. William Tully produced, on March 1st, 1824, at the instigation of the late Dr. Goring, his triple glass,  $\frac{1}{4}$ -inch focal length, it being the first achromatic combination for the microscope made in this country. But in the following year, on Mr. Lister showing him the disadvantageous figure of this construction, he altered it to his well-known nine-tenths. This glass had an aperture of 18 degrees, and worked well with eye-pieces to about 120 linear. Subsequently a second smaller triplet was placed before the nine-tenths glass, and a power was obtained, with beautiful definition, of 300 linear, with a pencil of light of 38 degrees. The glasses thus combined were about equal to a lens of three-eighths of an inch focus.†

With a happy combination of mathematical knowledge and practical experience, Mr. Lister continued to pursue the subject, and in the year 1830 he published in the "Philosophical Transactions" his paper on 'Aplanatic foci of the double achromatic object-glass, with other properties belonging to it, and a means derived from them of correcting by combination both spherical and chromatic aberration and coma.' Upon this communication has been based the whole of the progressive improvements to their present state of perfection. Although the author of this paper has not since published the further fruits of his labours, he has continued his exertions, and the results have been freely communicated to those celebrated makers among our own countrymen, who have aided and assisted him by their abilities in obtaining the beautiful achromatic combinations, which are now so abundant among our ablest anatomists and naturalists.

Mr. William Tully, who led the way in the manufacture of achromatic combinations, died about the close of the year 1835. At this time Messrs. Ross and Powell had taken up the manufacture, but without much advance on the first simple application of the principle until the beginning of 1837, when, at the suggestion of Mr. Lister, Mr. Ross constructed a differently-arranged combination, but on the same basis. It consisted of two double and one triple compound lens. This combination was successfully worked out, and was designed to produce a great increase of defining power; and it was at this time that the thought occurred to Mr. Ross to leave the front lens moveable, so that by varying its distance from the others, the glass might be adjusted either for covered or uncovered objects.

In the summer of the same year a new construction, composed of two achromatic lenses for a lower power, was suggested by Mr. Lister, and executed by Mr. Ross. In 1843, Mr. Ross constructed a combination of two triplets and one doublet, by means of which an increased angle of aperture and improved definition were obtained. One or the other of the above combinations are now employed by our three chief makers, Messrs. Powell and Lealand, Ross, and Messrs. Smith and Beck, to whom Mr. Lister also communicated the results of his experience in the construction of achromatic combination, each occasionally surpassing the others in the quality of the glasses; and their successive exertions have resulted in that superiority of the numerous and beautiful combinations which they have produced over all others in the Exhibition.

To Sir David Brewster we are indebted for many valuable suggestions for the improvement of the instrument, especially for the best method of illuminating by transmitted light, by the application beneath the stage of achromatic combinations, in place either of simple reflection of light from plane or concave mirrors, or of its concentration by means of the Wollaston condenser. By this method of illumination, minute and delicate objects during examination are presented to the eye under the most favourable circumstances, and a beauty and correctness of definition obtained which no other mode of illumination is capable of producing.

To the same source we are likewise indebted for the valuable application to the microscope of the apparatus for the polarization of light, which has so powerfully assisted us in the investigation of delicate and transparent animal and vegetable tissues.

In conclusion, it may be observed that the low-priced instruments exhibited by Messrs. Ross, and Smith and Beck, are deserving of high commendation. The brass-work is good in principle, steady and free from tremor in operation; and the powers, varying from 1-inch to a quarter-inch focus, inclusive, are by far the most generally useful in the whole range of microscopic combinations, especially for educational purposes.

It must be remarked that it is advisable that the angle of aperture of the combinations should not be extended to its utmost possible limit, when destined for the ge-

\* Exordium to "Microscopic Illustration," 1829.

† See "Quarterly Journal of Sciences" for 1825, No. 37, p. 132; also for 1827, No. 41, p. 265. Specimens of these

combinations are still in the possession of Messrs. Lister, Bowerbank, and Loddiges.

neral purposes of natural history or anatomical investigation.

Combinations of high power, and extremely extended angles of aperture, are excellent in developing one class of test objects, viz., minute lines or dots on plane surfaces, and admirably demonstrate the high perfection to which such glasses are capable of being carried by scientific opticians; but such combinations, with a less angle of aperture and more penetrating power, are far more generally useful and valuable to the minute anatomist and the naturalist.

In regard to the brass-work, we may observe that the qualities especially requisite in the stand of a microscope are simplicity of construction, portability, combined with sufficient weight to ensure safety and steadiness, with smoothness and accuracy of action in all the working parts, and such a construction as to distribute any tremor that may be communicated to the instrument equally over its body, stage, and other working parts. These desirable points are admirably attained in the form suggested by Mr. George Jackson, and adopted by Messrs. Smith and Beck, Ross, and other makers. For purposes of delineation, Næchet's (France, No. 1370) form of prism is more advisable than that of Wollaston's, as the former having one reflection less than the latter, presents the image to the eye in an erect instead of an inverted position.

We now proceed to discuss the particulars of each instrument.

ROSS (No. 254, pp. 435, 436) exhibits a microscope, the mechanical parts of which are exceedingly good: the movements are very smooth and true; the stand is on a plan which is solid and steady, and at the same time not cumbersome. The object-glasses are constructed with different kinds of glass in the different compound lenses, forming a combination so as to double up the secondary spectrum, and this is done so well that scarcely any separation of colours can be detected. The angular apertures of the object-glasses examined are as follows:—

|                      |               |
|----------------------|---------------|
| 1-inch focal length, | 27' aperture. |
| $\frac{1}{2}$ -inch  | 60'           |
| $\frac{1}{4}$ -inch  | 113'          |
| $\frac{1}{8}$ -inch  | 107'          |
|                      | 135'          |

Both the half-inch and the one-eighth of an inch foci are purposely made of smaller proportionate aperture than the quarter-inch, or the one-twelfth of an inch, as in all lenses of large aperture, the image becomes indistinct from the slightest change of focus:—and so, unless an object be an absolute plane, it is impossible to see the whole field tolerably distinct at once with an object-glass of large aperture. In the set examined, the inch, the half-inch, and the one-eighth of an inch, are intended for the general examination of objects; and the one-fourth and one-twelfth of an inch for the examination of minute structures. The object-glasses are first-rate. A Council Medal was awarded to Mr. Ross.

SMITH AND BECK (No. 253, p. 435) exhibit a microscope, the stand of which in appearance is not highly finished, but their forbearance to expend time and money on elaborately finishing the non-working part has been adopted on the strong recommendation of some of the oldest naturalists in London, in order that students may acquire instruments with first-rate glasses at the least possible expense, and that such instruments may be brought within the compass of those whose means are limited. The stand is excellent in principle: the body, stage, and appliances beneath are all carried on one stout cast bar, on the recommendation of Mr. E. Jackson, by means of which the centring of the achromatic illumination is rendered easy and certain, and on any tremor being communicated to the instrument, it is equally distributed over the whole of the working parts.

The lever motion to the stage of this instrument is the most easy and generally useful that has yet been applied. If used with the right hand, while the quick and slow adjustments to the focus are worked with the left, there is no animalcule that cannot be readily followed, however fitful and rapid its movements; and any globule of blood

pursuing its course through the most tortuous of the capillaries, can be steadily and easily traced, and every alteration of its form observed during its passage through these minute vessels. The field of view may also be swept horizontally or perpendicularly, and the most delicate micrometrical measurements made with great ease and precision. This stage is the invention of Mr. Alfred White; the rabbited groove on which the body moves was suggested by Mr. George Jackson, at whose recommendation the fulcrum of the stage movement was fixed to a spring, instead of to a rigid bar. The simplicity and efficiency of the whole of this stand are highly commendable. The object-glasses examined were of first-rate quality, and were as follows:—

|                              |                        |
|------------------------------|------------------------|
| $\frac{3}{4}$ -inch focus of | 45' aperture.          |
| $\frac{1}{2}$ -inch          | 70' to 75' aperture.   |
| $\frac{1}{4}$ -inch          | 60' aperture.          |
| $\frac{1}{8}$ -inch          | 100' to 105' aperture. |

They are beautifully corrected for spherical aberration, but the secondary speculum has not been much diminished. The half-inch focus of 70' aperture is a wonderfully fine combination, easily showing objects, considered difficult for a one-eighth inch focal length a little more than a year since, and bearing the application of the higher eyepieces in an unprecedented manner.

Smith and Beck also exhibit all that is necessary for the mounting of microscopic objects, as cells, slips, thin glass, fluids, covers, &c., and a few preparations as specimens. There is, also, a new form of cabinet, for the reception of objects, the names of which may be exposed, by means of porcelain labels with which they are furnished, and from which the pencil-writing can be easily effaced.

There are two tables with revolving tops, by which the microscope can be turned readily round for the convenience of examination by different observers, and thus rendered a social instrument. The microscopes are furnished with portable silver reflector and annular condenser, which exhibit transparent objects upon a dark ground. (This invention was made by Mr. Wenham, and Smith and Beck claim its first execution.) A Council Medal was awarded to Messrs. Smith and Beck.

VARLEY AND SON (No. 257, p. 436) exhibit a microscope, the stage of which is moved by parallel rods, with ball and socket joints, which arrangement gives an equable motion in all directions, and is specially adapted for the examination of living objects. A second microscope is exhibited, adapted for receiving vials in which aquatic plants or animalcule may be kept in a living state for any length of time. The plant is secured to one side of the vial by a piece of cork, and thus is within the reach of the microscope. The vial is kept full of water, and is only corked when used, at which time it is held in a jacket to cut off all extraneous light; a dark chamber projects from it, opposite to the magnifier, so that a single beam of light may be made to fall upon the part under examination.\* A third microscope, of a simple construction, is also exhibited, chiefly intended for beginners.

Varley's lever stage is very much more complex than White's; and as the lever is placed behind the stage it is less convenient to use.

KING (No. 287, p. 439) exhibits a microscope stand, with micrometers and goniometers. It has a pyramidal tripod, with stage traversed in rectangular planes by micrometer screws. The parts of this instrument are so arranged that its weight is equally distributed over the base, and when inclined at its working angle, the principal weight is below the point of suspension, and the stand is steady and good. The traversing-stage is furnished with divided scales and verniers. The workmanship throughout this instrument is of the first order. It is furnished with many ingenious applications of subsidiary instruments, and of apparatus specially adapted to the examination of objects by polarized light, and goniometric apparatus for measuring the angles of microscopic crystals. The mode of illumination, by a prism

\* This instrument is fully described in the "Transactions of the Society of Arts."

worked into convex spherical surfaces, is also worthy of notice. The Jury considered Mr. King as well deserving Honourable Mention.

PRITCHARD (No. 248, p. 435) exhibits an old-fashioned achromatic microscope, with 14 different object-glasses. The working of the mechanical parts is very good. This form of instrument is that which led the way in the great advance that has been made in the microscope by the introduction of achromatic object-glasses. The Jury voted Honourable Mention to Mr. Pritchard.

LADD (No. 291A, p. 440) exhibits a microscope furnished with chain and spindle movements, in place of rack and pinion. This movement has been applied to the microscope many years since, by Mr. Julius Page. The motion is smooth, and totally free from loss of time, and is likely to stand well the effects of constant use. The Jury award Honourable Mention to Mr. Ladd.

PILLISCHEER (No. 269, p. 437) exhibits a large microscope stand, which is good for its price, but unnecessarily large and inconvenient for use. He also exhibits two small microscopes.

JACKSON, E. and W. (No. 258, p. 436) exhibit plain and excavated slips of glass, sections of tubes of various forms, for the construction of cells for mounting wet preparations, and thin glass for covering them, of various thicknesses. These materials are exceedingly useful for scientific microscopists.

HUDSON (No. 256, p. 436) exhibits microscopic objects intended for the use of the medical student, physiologist, and naturalist.

HETT (No. 249, p. 435) exhibits a variety of admirably-injected microscopic objects, illustrating the utility of the microscope to the physiologist. A Prize Medal was awarded to Mr. Hett.

POULTRON (No. 252, p. 435) exhibits some well-executed microscopic objects, with drawings to illustrate their structure.

STARK (No. 281, p. 438) exhibits microscopic objects, mounted in *gutta serena* cells, instead of glass; and also slides for exhibiting opaque objects.

SHARP (No. 308, p. 442) exhibits a set of high power lenses, ten in number, for a microscope from one-tenth to one-hundredth of an inch focal length.

SHADBOLT (No. 677A, p. 469\*) exhibits a sphero-annular condenser, for concentrating light on transparent objects while under microscopic examination, the object alone being illuminated whilst the field of view is dark. A Prize Medal was awarded to Mr. Shadbolt.

The principle of this condenser was suggested by Mr. J. F. Wenham, of Brixton, in his parabolic condenser. Mr. Shadbolt's condenser carries out Mr. Wenham's principle, with the advantage of superior reflecting arrangements, greater facilities of construction, and less liability of derangement.

Other microscopes are exhibited by FIELD and SON (No. 250, p. 435), ELLIOTT and SONS (No. 320, p. 443), WATKINS and HILL (No. 659, p. 466\*), ABRAHAM (No. 263, p. 436), GRIFFIN (No. 457, p. 463); but they are not such as demand especial notice.

Let us now turn our attention to the microscopes exhibited by France; and first in order is NATCHET (France, No. 1370, p. 1242). The object-glasses, though inferior to both those of Ross, and Smith and Beck, are by far the best of the foreign ones. They vary from a focus of one inch to that of one-eighteenth of an inch. The following were examined; that with—

|                 |   |
|-----------------|---|
| 1 <sup>st</sup> | of an inch focal length, has an aperture of 134°. |
| 1 <sup>st</sup> | " " " " 108°.                                     |
| 1 <sup>st</sup> | " " " " 88°.                                      |

In all of them the spherical aberration is not corrected; and although the method of adjusting by the separation of the lenses, invented by Ross, is adopted, yet the system is such that they are not correct at any distance. The workmanship of the stand is very good; and there are two ingenious forms of microscopes exhibited. One has the object-glass below the stage, with the tube inclined at a convenient angle and a reflecting prism for the examination of chemicals, or for dissecting transparent objects under fluids. The other is a dissecting micro-

scope, with the body inclined in a convenient direction, and the image erected by reflecting prisms, so as to enable an observer to look in a convenient position whilst dissecting an object in fluid, which must be kept horizontal. A Prize Medal was awarded to M. Natchet.

Some microscopes, excellent for their price, are exhibited by BERNARD (France, No. 762, p. 1217). These instruments are the cheapest in the Exhibition, though none are of the first order. Honourable Mention is awarded to M. Bernard.

CHEVALIER (France, No. 1729, p. 1269) exhibits a microscope, with indifferent object-glasses. The workmanship of the mechanical part, however, is very good, the mode of mounting is excellent, and the instrument is convenient for all kinds of microscopic observations. The Jury voted Honourable Mention to M. Chevalier.

Some excellent microscopes, for their price, were also exhibited by BUNON (France, No. 443, p. 1194).

MERZ (Bavaria, No. 30, p. 1100) exhibits a microscope, the mechanical parts of which are beautifully executed. The object-glasses are of small aperture, and the spherical aberration is not corrected. The one-twelfth of an inch focus has an aperture of only 65°, and the one-eighth of an inch that of 55° only.

HAZART (America, No. 16, p. 1433) exhibits a large instrument, furnished with very deep Huygenian eyepieces, giving the usual extensive field obtained by such; it has, besides, two convex lenses in the body for enlarging the field of view. Neither chromatic nor spherical aberration is properly corrected, and the workmanship is not good.

PICK (Russia, No. 170, p. 1372) also exhibits a microscope, but it is an indifferent instrument.

We will now speak of some of the uses of the beautiful instruments we have just described; the most important illustration of their utility in the Exhibition is shown by LEONARD (No. 306, p. 442), in his correct representation of many different substances, &c., when highly magnified. He has selected several articles of food in daily use, also the substances with which they are sometimes adulterated, &c., as in the subjoined list.

#### Frame 1.

1. Transverse section of raw coffee berry, magnified 16 diameters.
2. Thin section of raw coffee berry, showing globules of essential oil, magnified 250 diameters.
3. Investing membrane, magnified 250 diameters.
4. Transverse section of chicory root, magnified 250 diameters.
5. Longitudinal section of chicory root, central fibres, magnified 250 diameters.
6. Longitudinal section of wheat grain, showing the embryo.
7. Wheat starch, magnified 250 diameters.
8. Investing membrane, 250 diameters.
9. Maize, longitudinal section, showing the embryo, magnified 12 diameters.
10. Maize starch, magnified 250 diameters.
11. Investing membrane, magnified 250 diameters.

#### Frame 2.

1. Horse-bean, transverse section, magnified 25 diameters.
2. Horse-bean, starch globules, magnified 500 diameters.
3. Horse-bean, investing membrane, magnified 500 diameters.
4. Potato starch, magnified 500 diameters.
5. West India arrow-root, magnified 500 diameters.
6. Sagø meal, magnified 500 diameters.
7. Rice (raw), magnified 500 diameters.
8. Rice (boiled), magnified 500 diameters.

#### Frame 3.

1. Healthy nurse's milk, magnified 1,200 diameters.
2. Pure cow's milk, magnified 1,200 diameters.
3. Cream of cow's milk, magnified 1,200 diameters.
4. Curd of cow's milk, magnified 1,200 diameters.

*Frame 4.*

1. Adulterated milk, magnified 1,200 diameters.
2. Calf's brains, magnified 1,200 diameters.
3. Milk with linseed tea, magnified 1,200 diameters.

*Frame 5.*

1. Human bone, a thin transverse section of the clavicle, magnified 95 diameters.  
Small portion of ditto, magnified 440 diameters.
2. Ostrich bone, transverse section, magnified 95 diameters.  
Small portion, magnified 440 diameters.
3. Turtle bone, transverse section, magnified 95 diameters.  
Small portion, magnified 440 diameters.
4. Hoof of horse, transverse section, magnified 95 diameters.  
Small portion, magnified 440 diameters.

*Frame 6.*

1. *Lepidosteus* scale, transverse section, magnified 95 diameters.  
Small portion ditto, magnified 440 diameters.
2. Sword-fish, transverse section of the sword, magnified 95 diameters.  
Small portion ditto, magnified 440 diameters.
3. Spine of Ray, from which shagreen is made, magnified 95 diameters.  
Small portion, magnified 440 diameters.
4. Human lung (healthy) injected, magnified 150 diameters.
5. Human lung (with tubercles) injected, magnified 150 diameters.

These anatomical and microscopical drawings deserve very Honourable Mention: the whole of their outlines and proportions have been executed by means of the camera lucida, so that they represent truly what the eye actually sees, and the details are finished with scrupulous accuracy; they are, therefore, among the most trustworthy representations of minute and elaborate tissues that perhaps have ever been executed.

TOPPING (No. 667, p. 467\*) exhibits five cases of microscopic objects. The contents of the first case are,—test objects adapted to the present state of microscopic science, ranging from two inches power up to one-twelfth of an inch of large aperture; also some of the most beautiful of the fossil infusoria.

Case 2—Contains fossil and recent vegetable structures.

Case 3—Dissections of insects. In this case are large dissections of the respiratory systems of the silkworm, caterpillar, and larvæ of beetles: all these are mounted in Canadian balsam.

Case 4—Sections of fossil teeth, bones, and shells, &c. In this case there is a diamond showing woody structure, and sections of oriental and Scotch pearls.

Case 5—Contains injected animal tissues.

Mr. Topping has mounted the greater part of these objects in Canada balsam: he remarks that this is the only medium which will permanently preserve specimens of natural history as objects for the microscope, and that he uses chrome yellow, instead of vermilion, for injections, with which material he can inject the minutest capillaries.

Mr. Topping's methods of mounting and preserving objects, are many of them of his own invention; he deserves to be distinguished above other exhibitors, as he was one of the first in the field, and perseveringly overcame many difficulties which others following after had not to encounter. His anatomical injections are admirable, as are also those of LIEBT (No. 249, p. 435), but in this branch neither of them is an original inventor, but are followers of John Quekett, Esq., of the Royal College of Surgeons. A Prize Medal was awarded to Mr. Topping.

BOURGOGNE (France, No. 434, p. 1199) has exhibited a case of microscopic objects prepared in the usual manner. They are mounted in Canada balsam, and consist of sections of wood, and entomological and other prepara-

tions, with a selection of salts to illustrate the polarization of light. The objects are well displayed, and carefully mounted. A Prize Medal was voted to M. Bourgogne.

NONNAT (Prussia, No. 77, p. 1053), of Barth, has exhibited his wonderful tracings on glass. The plan adopted by him is to trace on glass ten separate bands at equal distance from each other, each band being composed of parallel lines of some fraction of a Prussian inch apart, in some they are  $\frac{1}{1000}$ th, and in others only  $\frac{1}{100}$ th of a Prussian inch separated.

The distance of these parallel lines form parts of a geometric series; thus—

|                |
|----------------|
| 0.001000 line. |
| 0.000857 "     |
| 0.000735 "     |
| 0.000630 "     |
| 0.000540 "     |
| 0.000463 "     |
| 0.000397 "     |
| 0.000340 "     |
| 0.000292 "     |
| 0.000225 "     |

To see these lines at all it is necessary to use a microscope with a magnifying power of 100 diameters; the bands containing the fewest number of lines will then be visible. To distinguish the finer lines it will be necessary to use magnifying power of 2,000, and then the lines which are only  $\frac{1}{1000}$ th of an inch apart will be seen as perfectly traced as the coarser lines. Of all the tests yet found for object-glasses of high power these would seem to be the most valuable. These tracings have tended to confirm the undulating theory of light, the different colours of the spectrum being exhibited in the ruled spaces according to the separation of the lines; and in those cases where the distances between the lines are smaller than the lengths of the violet light waves, no colour is perceived; and it is stated that if inequalities amounting to  $\frac{1}{100000}$ th line occur in some of the systems, stripes of another colour would appear in them.\* A Prize Medal was awarded to Mr. Nobert.

LENDY (Sardinia, 60, p. 1304) has exhibited several dies or minute copies on silver and steel, of various devices. These specimens of minute and excellent workmanship are produced by a machine invented, but not exhibited, by Mr. Lendy. By its means any model, however elaborate, varying in size from 7.87 inches to 0.039 inch in diameter, may be reduced to one-fiftieth of its original size, a degree of minuteness which renders the copies so reduced almost imperceptible to the naked eye. On subjecting them, however, to examination by the microscope, they are found to be composed of lines of all but unparalleled delicacy and distinctness.

Mr. Lendy, who has been for many years engraver to the Royal Mint at Turin, has originated this ingenious invention, for the use of banks, mints, goldsmiths' companies, &c., with a view to the avoidance of counterfeits. We may particularize the following dies or punches which are exhibited:—

A royal crown engraved on silver, and very elaborate, the lines within side being so fine, that a common hair covered five of them. The same design in relief is also exhibited.

A ducal crown engraved on silver, and surrounded by a gothic frieze, executed with sharpness and precision never before equalled in so minute an object. The same design in relief is also exhibited.

A coat of arms containing a gothic "R," surrounded by a gothic frieze, and engraved on steel, 0.013 inch in diameter; in its execution it is as graceful as distinct. A similar design in relief is also exhibited.

Another ducal crown on steel, equally good with the preceding, is exhibited, as also one in relief.

Upon steel a copy of Mr. W. Wyon's medal (the design of which is a portrait of Her Majesty, surrounded with the words Victoria, D.G. Britanniarum Regina F.D.), it is 0.06 inch in diameter, the original being

\* See Poggenдорff's "Annalen" for 1846, and "Proceedings of the Royal Society," April 10, 1851.

1·8 inch in diameter. This is a most elaborate work, and bears examination well by high powers.

This invention, apart from its great ingenuity and the perseverance by which it has been originated, promises to be of great utility in reducing standard works with accuracy only exceeded by a degree of minuteness calculated to render any attempt at counterfeit next to impossible.

#### *Object Glasses for Telescopes.*

SIMMS (No. 741, pp. 475\*, 476\*, 477\*) exhibits several achromatic object-glasses; viz., one of 9 inches aperture, two of 8 inches aperture, one of 6·9 inches aperture, and one of 4 inches aperture. The largest which is exhibited is entirely of English manufacture, and the discs, both of flint and crown, were made by Messrs. Chance, of Birmingham. In all the remaining glasses, the crown is of English—and the flint of foreign—manufacture. The object-glasses are altogether the work of the exhibitor, and on examination were found to be good.

It is observable that the crown glass in all these specimens has a greenish line, and Mr. Simms states, with reference to this particular, that he has found from experience (as might be expected from the extinction of one extreme, and consequent shortening of the total spectrum), that there is less irrationality between this kind of crown glass and the denser kind of flint, than between the same specimens of flint and any other crown or plate glass that he has been able to procure. We understand Mr. Simms' practice in determining the corrections required for achromatism consists in using that part of the spectrum which is included between the lines B and G; he finds, however, differences of small amount, sufficient to produce a sensible effect upon the results, between discs of glass sent to him at the same time, and which he supposes are prepared, if not at the same time, at least of the same materials.

The following are the specific gravities, &c. of specimens of flint and crown glass manufactured by Messrs. Chance and Co., of Birmingham:—

| Kind of Glass. | Specific Gravity. | Index of Refraction B. | Index of Refraction G. | Dispersive Power B. to G. |
|----------------|-------------------|------------------------|------------------------|---------------------------|
| Flint —        | 3·583             | 1·6109                 | 1·6336                 | 0·036                     |
| Crown —        | 2·539             | 1·5128                 | 1·5274                 | 0·028                     |

To Mr. Simms the Jury consider very great merit is due, not only for the exquisite workmanship displayed in every instrument exhibited by him, but also for the several new inventions and arrangements which, by the greater facility they afford to observation, cannot fail in the advancement of astronomy. The Jury unanimously voted a Council Medal to Mr. Simms, which award was passed unanimously by the Group; but, unfortunately, was not confirmed by the Council of Chairmen; consequently the medal which Mr. Simms will receive is not that which, in the opinion of the Jury, is due to him.

GOUDARD (No. 274, p. 438) exhibits an object-glass.

BURON (France, No. 443, p. 1199) has exhibited an achromatic glass 7·5 inches diameter and 10·8 feet focal length; the crown and flint glass for which were made by the late M. Guinard, of Paris, and the curves according to the theory of Sir John Herschel, and is designed to show stars of the eleventh magnitude. • It was not tried by the Jury on account of its tube being delayed at the Custom-house under a very heavy charge.

#### *Solid Eye-pieces.*

READE (No. 254A, p. 436) exhibits two solid eye-pieces. They consist of three lenses, the anterior and posterior being double convex of crown glass, and the intermediate one double concave of flint. The contact surfaces are cemented together, and consequently the action upon the rays of light is similar to that of a single lens. They are applicable to all astronomical instruments, micrometers, and microscopes, and also as a general magnifying power.

The novelty of the solid eye-piece consists in its construction, by which a large and flat field of view is obtained, together with the removal of spherical and chromatic aberration. These advantages are obtained by means of the great thickness of the flint lens, which is a perfectly new feature in the construction of eye-pieces.

Sir David Brewster's achromatic sphere which he proposes to use as an object glass for the microscope, approximates to this form, but the field is not flat. The general mathematical expressions for the curves of the solid eye-piece have not as yet been fully worked out; but it may be stated as a rule for the practical optician, that the radii of the outer curves of the two convex lenses, must be in the proportion of the dispersive ratio of the crown and flint glass employed on each eye-piece, and the inner contact surface must be such as by experiment will perfect the achromatism. The solid eye-pieces exhibited have focal lengths of 0·5 inches and 0·75 inches, and it happens that while the eye-piece of shorter focal length is barely brought up to a flat field of view, the one of longer focal length is carried rather beyond, and is therefore slightly over corrected. These small errors are upon the whole satisfactory, inasmuch as they show that a truly flat field is attainable.

Sir David Brewster observes in his "Treatise on Optics," that "achromatic eye-pieces, where one lens only is wanted, may be composed of two or three lenses, exactly on the same principle as object-glasses; such, indeed, as the cemented triple object-glass made for the microscope, which was described by the Rev. J. B. Reade some years ago, in a paper read before the Royal Society, as being an efficient eye-piece for telescopes:—in fact, the then best known form of a vertical single lens; but, the smallness of the field is an insuperable objection to its use with a micrometer. The larger field of view now obtained in the solid eye-piece is solely due to the thickness of the flint, which causes the image of the object-glass, where the eye is placed, to be formed so near the eye-piece that its diameter is seen under a considerable angle; and it is found that in the lower powers the diameter of the field of view is larger than in the ordinary negative eye-piece."

The positive eye-piece almost universally used, is known as Ramsden's: the field is flat, which is requisite for a measuring instrument, but it is far from being free from colour.

The Astronomer Royal states\* that the positive eye-piece at present used is not achromatic, and cannot be made so; and considerable inconvenience is occasioned by this defect, for when the object is not far from the centre of the field, the chromatic confusion is much greater than that produced by spherical aberration; since it varies as the distance from the centre, and in this confusion there is nothing to point out the centre of the coloured line.

The new solid eye-piece is therefore looked upon as an important addition to the working apparatus of an astronomer, inasmuch as the great evil of chromatic confusion, which prevents any accurate measurements at the extremities of the field, does not here exist at all, but the webs of the micrometer, though ever so distant, may be seen as fine black lines. The field of view is also free from illumination by false light; no light is lost, as in the usual construction by inner reflection from the surfaces of the lenses,—and there is no formation of the false image or ghost of planets, nor of the bright stars, which injures the best part of the field.

An examination of this eye-piece, as applied to a telescope, in comparison with the action of the ordinary eye-pieces applied to the same telescope, made by Mr. Glaisher, extending over a period of three hours, fully impressed him with its superiority; the field of view was black, and the stars appeared as very bright points. In consequence of the purity of the achromatism it will probably be found that in determining the colours of fixed stars, these eye-pieces may be of essential service. • The Jury awarded Mr. READE the Prize Medal.

\* See "Cambridge Philosophical Transactions," vol. iii. p. 56.

*Optical Glass.*

The disc, of 29 inches in diameter, exhibited by Mr. CHANCE (p. 477\*) having undergone a partial examination by the Jury, it was considered that a satisfactory opinion could not be formed of it, owing to the irregularities in its surfaces, until it had undergone the operation of polishing, so as to give it a plane, or nearly plane figure. This operation having been performed by Mr. Ross, and the disc being reported by him fit for further examination, it was agreed to subject it to such on Tuesday, the 9th of September 1851, for which day (it being considered by the Committee desirable to have the attendance of as many of the Jury as could be brought together) a Jury summons was issued, which was responded to by Professors Potter and Colladon, who attended with the Committee, consisting of Sir J. Herschel, Mr. Glaisher, and Professor Miller. Mr. Ross, Mr. Simms, and Mr. Bouteins (the latter on the part of Mr. Chance) were also present at the examination.

The dimensions of the disc were as follows:

|                        |                     |
|------------------------|---------------------|
| Largest diameter . . . | 29½ inches.         |
| Shortest „ „ „         | 29 „ „              |
| Thickness, from . . .  | 2·2 to 2·25 inches. |

Its weight was stated to be somewhere about 200 lbs. The specific gravity about 3·56 . . . 3·58. The surfaces were highly polished and brought to a figure very slightly deviating from true planes, so that no deceptive appearance of striation could possibly arise from irregularities in their surfaces.

The disc was first examined by inspection through faces cut upon its edges. These faces had not been re-polished, or brought to a true figure; so that nothing could be gathered from this examination, but that no offensive striæ were seen through them.

The state of the disc, as to tension from imperfect annealing, was then tried by passing polarized light through it at right angles and at obliquities, and analyzing the emergent beam by tourmalines and Nicol prisms. It was found to be very remarkably free from indications of tension, only a feeble gleam of whitish light becoming perceptible on some portions of the edges, which might have arisen from the heat of the hands of the persons employed to lift and keep it in position.

It was then placed on edge, and tested by looking very obliquely through it at objects offering broad lights and shadows. During this examination a group of striæ became visible at a spot whose position on the glass was marked, and to which and its near neighbourhood they seemed to be limited.

To trace the limits of this group, and to subject the whole disc to a more rigorous and delicate scrutiny, it was set upright on a table; the room (the Indian tent) darkened, a candle placed 7 or 8 feet behind the disc, and a convex lens of about 5 feet focus and 6 inches diameter, of extremely pure glass, held between the candle and the lens close to the latter. The eye of the observer being placed before the disc in the place of the image of the candle, so as to cover the lens with a glare of light; striæ, it is well known, become distinctly apparent, if existing, in any part of the disc so covered.

Every part of the disc in succession, beginning from the centre, and proceeding outwards in radii was thus carefully examined for striæ. With the exception of a hair or thread, perfectly definite, and of a looped form,

thus, near the centre, and next of the smallest importance in an optical point of view, and a few other trifling threads, originating apparently in minute sand-grains, in various points, and also utterly inoffensive, no appearance of striæ whatever could be discerned over any part of the disc, but at and in the immediate neighbourhood of the place marked.

No bubbles of any consequence were noticed in this examination, or on ocular inspection.

Attention being concentrated on the group of striæ thus pointed out, it was found to occupy a space (at its utmost extent) of 6½ inches in length and 2½ inches in breadth, beginning at about 1½ inches from the edge, and having its longer dimension directed towards the centre. The

whole of this space was by no means equally affected, and the most objectionable portion was much more limited. This was situated not far from the middle of the space in question; and it was proved decisively that the seat of the worst portion (or nucleus) of the group was almost close to one of the surfaces, by the test of parallax, viz., by placing a mark on the surface next the eye on the apparent place of the nucleus, and then tilting the disc right and left. One side (A) being towards the eye, the mark and nucleus remained coincident; and on reversing the disc, and bringing the other side (B) nearest the eye, and making a fresh mark (effacing the former), they coincided only when the visual ray passed perpendicularly through the disc, the nucleus passing parallaxically behind the mark, from side to side, on inclining the disc.

As the disc would have to be worked into a concave or convex-concave lens, by which its thickness in the centre would be reduced at least an inch, there is little doubt, therefore, that by acting on that surface near which the nucleus is situated, it, and much of the neighbouring striæ, which are evidently connected with it, would be ground out. Such is the decided opinion of Mr. Ross. In that case, as the whole area occupied by the striated region does not exceed 0·019, or less than one-fiftieth of the total surface of the glass, it might very reasonably be expected that, if worked into an object-glass, the mass of good light would so far overpower the injurious effect of what striæ might remain, as to give a very satisfactory result, and that for many purposes of high astronomy it might prove extremely efficient.

On the other hand, if it should be resolved to sacrifice the defective portion, or so much of it as to leave but a very trifling part of a comparatively inoffensive region still encroaching on the edge (suppose a spot of an inch diameter), it would be practicable to cut out from the whole disc a smaller one of 22 inches (29 — 1½ — 5½) diameter, apparently quite perfect in every other part, and of 2·2 inches in thickness. But as this thickness is superfluous, it might be found practicable, by cautiously heating the glass to the softening point, and applying pressure, to extend it in surface whilst reducing its thickness to 22-29ths of its present amount. Supposing this operation successfully performed, and that in the manipulation some portion of the good glass adjacent to the striated part being retained could be pressed inwards, so as to drive out the small striated corner, a disc of 25 inches diameter, of apparently perfect flint glass, would be produced.

The great object-glasses of Pulkowa, and of New Cambridge in the United States, do not exceed 16 inches. Compared to this, a 25-inch, or even a 22-inch object glass would be as great a stride in advance, as the Pulkowa lens is beyond the largest achromatics previously constructed.

On these grounds the Committee have had no hesitation in recommending that a Council Medal be given to Messrs. CHANCE for this disc. They desire it to be clearly understood, however, that no examination to which a disc of glass *unworked* can be subjected, will afford more than a reasonable probability that a telescope *worked* from it shall turn out perfect; since, independently of peculiarities in the glass which this kind of examination may fail in detecting (though no better has yet been devised), the perfection of the resulting instrument will still be dependent on that of the crown lens and of the optical workmanship.

M&S (France, No. 656, p. 1209) has exhibited specimens of a new kind of glass; the basis of which is the oxide of zinc, a certain quantity of borax, a boric acid being added, to give the glossy character for which the boric compounds, no less than the silica, are so eminently remarkable, combined with an easier fusibility. As a material in the arts, the Jury have no further concern with this glass, than as regards its probable utility in the construction of telescopes, prisms, and other optical apparatus, for which it extreme limpidity and total freedom from colour, and, so far as appears, from veins and striæ, seem eminently to fit it, and which have induced them to propose its being rewarded with a Medal. The

low dispersive power of the zinc compounds, points to its use as replacing the crown glass in achromatic telescopes. Suppose it should be found practicable (and the experiment is recommended to the attention of artists, as one in which, when tried on a very small scale, some success has actually been obtained) to form colourless and uniform glasses in which fluorine enters as a distinguished ingredient, in combination with silica, alumina, or other materials; the combination of such glass, as a convex lens, with this new material of Mr. Maës, or with ordinary crown glass, as a concave, might be expected to produce achromatic object-glasses of a very perfect description. The coloured dispersion to be removed, being much less than that of crown glass, owing to the peculiarity of the fluorine compounds, which beset the manufacture of flint glass, arising from the intense solvent power of the oxide of lead on the crucibles, and give rise to striae and veins, would be evaded. Mr. Maës, besides two prisms of his new glass, of the most limpid purity and perfect freedom from veins or striae, has exhibited two discs of  $4\frac{1}{2}$  and 7 inches in diameter, prepared for optical use. In an examination, through faces cut on their edges, no veins or striae were detected, and, consequently, should there arise no objection to this material, either in point of durability or facility of working, it will probably prove very valuable for the use of the optician. Some small astronomical lenses, in which zinc is substituted for crown glass, are also shown. Its refractive index is 3.285, and its dispersive ratio, as compared with a flint glass of specific gravity, is as 3.55, to 0.6502.

It has been long a theorem in every treatise on optics, that the achromatic union of the whole spectrum cannot be accomplished by any combination of dispersive media, and that two media of different dispersions enable us to unite but two rays precisely, the rest only approximating, leaving two masses of uncentred colour, the one converging to a longer, the other to a shorter focus than that of the united rays. A fitting combination of three media, admits of the exact union of three rays at different points of the spectrum, and a very much greater approximation to union among all the rest, provided their scales of action on the different rays of the spectrum differ sufficiently. In this point of view, the new glass, whose dispersive action on the spectrum, from the introduction of a new metallic oxide, may very reasonably be expected to differ from those of the crown and flint glass, will, perhaps, become available in this third medium, so long a desideratum in optics; and its use may open a new field in the theory of the construction of telescopes. Should it prove (owing to the boracic acid it contains) less durable, or more open to atmospheric corrosion than the other media, its place in a compound lens will be intermediate, as a defence from air or moisture, and one of the conditions of the structure may be that of a perfect coincidence of one or of both its surfaces, with those of the adjacent lenses, to allow of cementing them. A Prize Medal was awarded to M. Maës.

DAGUET (Switzerland, No. 75, p. 1271) has exhibited discs of flint glass of  $15\frac{1}{2}$ ,  $12\frac{1}{2}$ ,  $10\frac{1}{2}$ , 9,  $7\frac{1}{2}$ , 7,  $6\frac{1}{2}$ , and 4 inches in diameter respectively. On examination, by chords and diameters, they were all found to be good; striae were suspected to exist in the largest; but, if so, it was in one diameter only, and but to small amount. A disc of crown-glass, of 7 inches diameter, and one of 4 inches, were examined, and found to be good; another, of  $6\frac{1}{2}$  inches, was less perfect. The specific gravity of the flint was stated to be nearly 4, and that of the crown to be from 3.5 to 3.6.

Mr. Daguet, by a process of his own, gives to flint-glass a degree of hardness not attained by any other manufacturer; his glass, particularly the flint, is in general use among all the best opticians, being distinguished both by its homogeneity and its peculiar property of resisting all decomposition by the action of air. The Council Medal was awarded to Mr. Daguet.

#### *Lenses and Prisms.*

BEYERLÉ (France, No. 765, p. 1217) exhibits many lenses ground with cylindrical surfaces; they are free from

spherical aberration, and give a true view on their whole surface; also long lenses, with the axes parallel, equally true throughout; they are useful in photographic registration of changes in the position of magnets, &c., as adopted by Mr. Brooke.

M. Beyerlé also exhibits lenses ground on curves of different foci, &c.; also many achromatic lenses of short focus. The working of these reflects high credit upon M. Beyerlé, and the Prize Medal was awarded to him.

JAMIN (France, No. 548, p. 1204) exhibits a fine assortment of prisms, chiefly crown; a large flint disc, and plane and concave reflectors, mounted on brass swing frames, of large dimensions. Honourable Mention was made of M. Jamin.

BERTAUN, Jun. (France, No. 1549; p. 1251) has exhibited some of the finest possible Nicholl's prisms; some slices of crystals, prepared to show that, in certain crystallized bodies, heat is unequally transmitted in different directions; with many other specimens of most difficult, yet beautifully cut prisms, reflecting the highest credit upon the maker. The Prize Medal was awarded to him.

BURON (France, No. 443, p. 1199) has exhibited various prisms.

#### *Lighthouses.*

CHANCE (Class XXIV., p. 477; Class X.) has exhibited a design for a lighthouse, consisting of a dioptric apparatus of the first order, and constructed with revolving lenses and catadioptric zones.

This apparatus combines the principles upon which the fixed and revolving dioptric lights of Fresnel were constructed, with an improved method of reflection, by which the use of metal reflectors is entirely superseded.

In the fixed dioptric light of Fresnel, the flame is placed in the centre of the apparatus, and within a cylindric refractor of glass, of a vertical refracting power, the breadth and height of the strip of light emitted by it, being dependent upon the size of the flame and the height of the reflector itself; above and below is placed a series of reflecting prismatic rings, or zones, for collecting the upper and lower divergent rays, which, falling upon the inner side of the zone, are refracted, pass through the second side, where they suffer total reflection, and, passing out on the outer side of the zone, are again refracted. The effect of these zones is to lengthen the vertical strip of light, the size of which is dependent upon the breadth of the flame and the height of the apparatus.

The system adopted by Fresnel, in his revolving dioptric lighthouse, is open to some objections. A large flame is placed in the centre of a revolving frame, which carries a number of lenses, on a large scale and of various curvatures, for the avoidance of spherical aberration. With the view of collecting the divergent rays above the flame, an arrangement of lenses and silvered mirrors is placed immediately over it. By this compound arrangement the simply revolving character of the apparatus is destroyed, as, in addition to the revolving flash, a vertical and fixed light is at all times seen; added to which a great loss of light must be sustained from the use of metallic reflectors.

The lighthouse constructed by Mr. Chance may be described as Fresnel's revolving light, rendered holophotal. It is divided into three compartments, the upper and lower of which are composed respectively of thirteen and six catadioptric zones, which produce the vertical strip of light extending the whole length of the apparatus, and is similar to that described as Fresnel's fixed dioptric light. The central or catoptric compartment consists of eight lenses of three feet focal length, each of which is the centre of a series of eleven concentric prismatic rings, designed to produce the same refractive effect as a solid lens of equal size. These compound lenses are mounted upon a revolving frame, and transmit horizontal flashes of light as they successively rotate. The motion is communicated to the frame by a clock movement, and performs one revolution in four minutes; consequently, as there are eight lenses, a flash of light is transmitted

every thirty seconds to the horizon. The system of a fixed light, varied by flashes from prisms, originated with Fresnel.

The apparatus is lighted by an Argand lamp, with four concentric wicks: it is provided with four sizes of burners, the largest of which is  $3\frac{1}{2}$  inches, and the smallest 1.6 inch in diameter, and is stated to consume 1 pound 10 ounces of oil per hour; carcel oil being employed.

The interior edges of the framework, carrying the catadioptric zones, are silvered; the workmanship is not characterized by any great degree of finish; a fact in its favour, as any great degree of finish, or adoption of ornament, would involve an increased outlay of capital without compensating advantages.

The glass of which the apparatus is manufactured is dark and of a greenish colour; this we are informed is due to its having been subjected, in melting, to a very high temperature, with a view of draining off the alkali, which, by rendering it dryer and harder, would prevent the exuding of moisture from the surface, a defect to which glass is liable when exposed to the air; it is, however, probable that the colour will have no injurious effect, as it is known that such tinge does not affect the transmission of light. The presence of striae, which are observable in many points, will, by scattering the rays, cause a loss of light to some amount.

WILKINS (Class VII., No. 157, pp. 326—328) has exhibited a revolving catadioptric apparatus for a lighthouse of the first class.

This, also, is constructed upon the holophotal system, and does not differ very materially from that exhibited by Chance. For the moveable cylindrical lenses, is substituted a single revolving cylinder composed of four lenses, alternated with an equal number of fixed ones, according to the succession of flashes to be produced during each revolution. A new arrangement is also introduced, whereby the friction rolls which revolve on two parallel planes, may be so fitted on an iron axis with regulating screws, that, when one part of the plate becomes worn, they may be adjusted to another part. The glass, though white in colour, is not more free from striae than that exhibited by Mr. Chance, and though great finish and ornament are discernible in the manufacture of the apparatus, these would seem to be rather objectionable than otherwise. For a detailed description, see Illustrated Catalogue, Class VII.

The Jury make Honourable Mention of this lighthouse.

#### *Physical Optics.*

DUBOSQ-SOLEIL (France, No. 1197, p. 1235) has exhibited Silbermann's heliostat. The principle of this instrument is quite different from that of S'gravesandes, which is that of making the perpendiculars to the reflecting plane, describe an oblique cone. In the instruments exhibited, the reflector, by a peculiar gimbal suspension, is always kept equally inclined to two axes, one of which is fixed, and directed towards the line which the reflected ray is to take; the other is kept by a clock motion always parallel to the sun's direction, the plane of the reflected ray being by the same gimbal suspension, kept perpendicular to the plane in which both these axes lie; thus the incident ray parallel to the one will be reflected parallel to the other.\*

DUBOSQ-SOLEIL (No. 1197, p. 1235) has also exhibited a saccharometer. A double gauge, formed by a rotatory-polarizing plate of quartz and Iceland spar, of which two semicircles, juxtaposed, and viewed through a telescope of about double magnifying power, are brought to exact coincidence of colour, by turning the spar. In this situation, the images are viewed through an empty tube, closed at either end with glass, and of a given length. The saccharine solution is passed in, and the quality of colour disturbed: the semicircles no longer match: they are then re-adjusted by sliding one upon the other two achromatized prisms of Iceland spar acting against each other, so as to have their difference of thickness out-

standing, the amount being estimated in parts of a finely divided scale, which is graduated so as to show, by inspection, the saccharine matter present. This is a beautiful and delicate instrument, carefully executed and well-finished.

DUBOSQ-SOLEIL (No. 1197, p. 1235) has also exhibited Bravais' helioscope, for the exhibition of all the phenomena connected with halos, parheliions, &c. This beautiful instrument consists of a clock-movement for the purpose of giving a rapid revolution to a vertical axis; two glass prisms (one hollow for the reception of water); a quadrangular prism, and a small arm carrying a mirror, all adapted for mounting on the vertical axis; two opaque plates of glass for the purpose of obscuring one or two sides of the prisms, as necessary, and a plate of glass mounted. To produce a representation of the parheliion, it is necessary to place a candle in a darkened chamber, on a level with, and 10 or 12 feet distant from, the glass prism on its axis of rotation, the prism having two sides covered. On looking in a horizontal direction, the parheliion circle will become visible. By obscuring one side of the prism, only three horizontal lines are seen; two being formed from the exterior and one from interior reflection.

To produce an imitation of the white parheliion, the candle is placed in the same position, and two sides of the prism are again darkened; when, on looking at the parheliion circle, at a distance of  $120^\circ$  from the candle, the white one will be perceived.

Coloured parheliions may be exhibited by means of the prism of water, viewed at an angle of  $20^\circ$  or  $25^\circ$ . One side of the prism being obscured, the coloured parheliion, red on the side near the candle, with a white train prolonged to  $15^\circ$  or  $20^\circ$ , will be seen.

To imitate coloured parheliions, formed at a distance of  $98^\circ$  from the sun, the arrangements are the same. By obscuring the prism, and looking at the distance of  $98^\circ$  from the candle, a coloured spot will be observed, red on the side opposite to the candle, and less bright than the parheliion.

The circumzenithal tangent of the arc may be imitated by means of the prism of water, the candle being lowered from its original position, and two sides of the prism darkened; on placing the eye in a proper position, the image will then appear reflected upon the ceiling. Several changes may be produced by simply turning the prism. The circumzenithal arc may be produced by the above arrangement, the position of the eye only being altered.

To imitate the antheion, it is necessary to make use of the quadrangular prism; its large transparent surface is turned towards the observer, and the candle placed a little above the prism, at the distance of six or eight feet from it. A small circular mirror is then so placed that its centre is on a level with the top of the prism. The eye, being situated behind the prism, will perceive a luminous circle described beneath its edge. If a little slip of paper be placed beneath, it will be perceived more distinctly without moving. By moving the position of the eye, several distinct phenomena will become visible. There are means of adjusting the apparatus, to render the image for a time permanently fixed. Other phenomena besides those detailed can be shown by this instrument, and great merit is due to M. Bravais, the inventor.

Dubosq-Soleil, besides these, exhibits a very great variety of delicately constructed philosophical instruments, for exhibiting the phenomena of polarized light and other physical experiments; such as a cyanopolarimeter, for observing the polarization of the sky; Arago's apparatus for exhibiting the interference of polarized light; Fresnel's screw for polarizing glass by compression; Babinet's goniometer, Brewster's stereoscope, &c.; M. Dubosq-Soleil also exhibits an apparatus, invented by himself, for fixing the charcoal points for electric light.

A Council Médal was awarded to M. Dubosq-Soleil.

#### *Spectacles and Opera Glasses.*

It is with regret we observe that exhibitors of spectacles in the British portion of the Exhibition have done nothing

\* See "Comptes Rendus de l'Académie," 1843, tome xvii., p. 1319.

more than exhibit a collection of shop goods, and have regarded the improvement of the glasses themselves as a matter of little moment. They have vied with one another in mounting spectacles in the finest and most flexible frames, and have produced articles finer and more delicate than any which have before been made. They have, however, with this exception, been content to follow in the steps of their forefathers, and have lost sight of the main object, in their desire to render these useful appurtenances to the sight as little visible and unsightly as possible. In the Foreign Section how pleasing a contrast is afforded by HENRI (France, No. 262, p. 1189) who, viewing the subject in the proper light, has possessed himself of a thorough physiological knowledge of the eye, whether healthy or otherwise, and using this knowledge as a basis for the exercise of his skill as an optician, has succeeded in making great advances, and, by a skilful adaptation of the principles of optics, has been enabled to manufacture glasses, the foci of which are so arranged as to suit almost every peculiarity of vision. The glass, itself, is also of great purity, and removes a fruitful source of the uneasiness and fatigue incident upon the use of spectacles.

Upon spectacles, as constructed by M. Henri, we have no objection to report, combining as they do the work of the optician with a knowledge of optics; but we cannot consider we are called upon to report upon spectacle-frames, or articles which have evidently been manufactured and exhibited with a purely commercial view.

HOWLEY (No. 290, p. 439) has exhibited spectacles of various kinds, chiefly remarkable for their durability of mounting, both as regards material and construction, some being of no greater weight than 11 grains; the whole weight, including glasses, not amounting to more than 2 pennyweights. The steel frames of these last resemble hair lines, and are imperceptible at no great distance.

WEAVER (No. 279, p. 438) has exhibited several pairs of spectacles, many of them distinguished by a mounting of extreme lightness; also a steel band frame, to be adjusted before the eyes, without pressing upon the nose.

BRATHWAITE (No. 283, p. 438) has exhibited several ventilating eye-shades, designed to allow a current of air to circulate freely between the shade and the wearer, and thus to obviate the collection of heated air in the neighbourhood of the eyes.

CHADBURN BROTHERS (No. 259, p. 436) has exhibited several pairs of elastic steel-framed spectacles, designed to combine lightness with durability, and spectacles for various purposes. These, as well as everything exhibited by Messrs. Chadburn, are remarkable for extreme cheapness, and in this respect they deserve Honourable Mention.

BAYLEY (No. 273, p. 438) has exhibited various spectacles, in mountings of gold and silver.

IXAMS (No. 278, p. 438) exhibits a solid piece of glass of a conical shape, or rather of the form of a frustum of a cone, ground at the base or larger end to a convex surface, and at the smaller end to a concave surface, intended for opera-glasses.

DIXEY (No. 271, p. 438) has exhibited a variety of spectacles, some of them remarkable for their lightness; a variety of eye-glasses, and several binocular opera-glasses.

CLARK (No. 276, p. 438) has exhibited spectacles adapted for use, if required, as an opera-glass.

ELLIOTT and SONS (No. 320, pp. 443, 444) exhibit specimens of blue steel and gold spectacles of a very light and flexible kind; also gold hand-spectacles, intended for use with one hand, and various specimens of opera-glasses.

HORNE, THORNTWHAITE, and WOOD (No. 220, p. 433), exhibit Smee's optometer, for ascertaining the refractory humours of the eye, and the required focus of spectacle glasses.

ABRAHAM (No. 289, p. 439) has exhibited various kinds of spectacles.

CALLAGHAN (No. 268, p. 437) a pair of steel spectacles. SOLOMON (No. 288, p. 437) a pair of eye-protectors.

WHITEHOUSE (No. 280, p. 438) various spectacles; a pair for sketching, mounted without a rim to prevent obstructing the vision.

YEATES (No. 332, p. 446), of Dublin, spectacles of the ordinary kind.

HENRI (France, No. 262, p. 1189) has exhibited several kinds of improved spectacles, for correcting the defects of vision; those for rectifying obliquity of vision (orthostatique) are made of steel, bronzed, and furnished with a moveable diaphragm, which may be shifted either right or left at will. They are designed for the cure of squinting, either converging or diverging. Spectacles for both requirements are exhibited.

M. Henri has also exhibited spectacles for preserving the eye-sight (conserves gardes-vues) designed for the use of persons suffering from weak eyes, ophthalmia, &c., and particularly adapted for the use of those who work much at night by artificial light.

With the skill of the optician, M. Henri has combined the knowledge of the oculist, and great praise is due to him for the improvements he has made in spectacles adapted to peculiar states of the eye; he has the further merit of being the only exhibitor of such spectacles in the Exhibition. The Jury considered him well worthy of Honourable Mention.

POULLOT (France, No. 966, p. 1226) has exhibited various spectacles in very fine and slender mountings.

As M. Pouillot considers a great part of the inconvenience experienced in the use of spectacles to be due to the weight of the mounting or frame-work, he has been induced to make various trials for its rectification, by endeavouring to combine stability with the least possible weight. He first contrived a pair of spectacles mounted in steel frames, filled with lead; but the steel proved to be too soft and the lead too heavy. After various attempts he completed several of tempered steel, and entirely without seam or solder, the weight of which did not exceed a quarter of an ounce—a weight in itself insufficient to cause inconvenience to the wearer. The exceeding lightness and comparative elegance of these glasses is designed to remove the prejudice existing against spectacles in general, owing to the reason before mentioned.

M. Pouillot considers that he has made spectacles which always preserve the visual ray in the centre of the glass; he has also exhibited metallic woven spectacles for the free admission of air to the eyes, which subdue the light and serve as a screen against dust, insects, &c., or any extraneous substance which might be injurious to the eye.

LEMERAY (France, No. 298, p. 1191), exhibits many very cheap spectacles and opera-glasses.

PATHEUX (France, No. 1412, p. 1243) exhibits a fine collection of opera-glasses, some of which have large object-glasses.

BRONX (France, No. 443, p. 1199) has exhibited a number of opera-glasses, both single and double, of which the mountings are of various materials, such as enamel, ivory, tortoiseshell, &c.

BUSCH (Prussia, No. 89, p. 1053) exhibits various spectacles, differently mounted; single and double opera-glasses, lenses, &c.

LATINSE (Belgium, No. 184, p. 1157) has exhibited various pairs of spectacles.

BAGEN (France, No. 25, p. 1172) spectacle glasses.

PLAGNIOL (France, No. 1679, p. 1257) spectacles of various kinds.

PICK (Russia, No. 170, p. 1372) exhibits a pair of spectacles.

#### *Dissolving Views Apparatus.*

ABRAHAM and Co. (No. 263, p. 436) exhibit a trinoptic prismatic lantern. The three lanterns are illuminated by a small circular wick, through the centre of which a tube passes for the purpose of supplying oxygen gas, by which means an intense light is obtained. A disc of 25 feet for each tube may be obtained, and each can be darkened to any extent, without any shadow on the picture. The three discs, by means of the prisms, can be thrown together, or they can be placed at various distances on the screen, forming one panoramic picture.

Abraham and Co. also exhibit a dioptric prismatic lantern, with two discs, which can be used as a dissolving apparatus.

CARPENTER and WESTLEY (No. 270, pp. 437, 438) exhibit a pair of phantasmagoria lanterns; a lantern with the addition of a microscope, together with a set of lenses to be used in conjunction with them; a series of subjects in outline, and various paintings adapted for dissolving lanterns.

HORNE, THORNTHWAITHE, and WOOD (No. 220, pp. 434, 435) exhibit a dissolving apparatus for the oxyhydrogen fire-light, showing the contrivance for dissolving the pictures; also an oxyhydrogen microscope, and a series of paintings for dissolving views. The novelty of this arrangement consists in the shutters being placed so that they cut off the rays where they cross in front of the lenses, by which means a more perfect dissolution takes place. The quality of the manufacture and the general arrangement of the various parts are good.

#### Photographic Cameras.

The camera is the principal instrument of the photographer, as by its means light is made to become a chemical agent.

This instrument, the invention of Baptista Porta, towards the end of the sixteenth century, was simply a dark chamber furnished with a single double-convex lens, fitted in a tube, and serving for the focal adjustment of the image. So constructed it was first applied to the copying of different objects, the outlines of which, as given by the camera, were traced upon the paper by a pencil; but the image was reversed. After a time this inconvenience was rectified by the use of a mirror; with an instrument of this kind, A. Canaletti, at the beginning of the eighteenth century, made the drawings for his fine pictures of Venice, which he consequently executed with a perfection of perspective so great as to be regarded as an illusion.

By degrees a lens concave towards the object and convex towards the image was adopted; the picture was thus rendered clearer, but the colours of the spectrum were not corrected. At length an achromatic lens was used, the flint glass being towards the object. M. Daguerre went a step further, and determined those relative proportions of the camera, which, for the most part, are still adopted; the interior being carefully darkened, for the purpose of avoiding casual reflection upon the field of view.

Mr. Ross, in addition, prepares those for portraiture with the greatest intensity yet produced, by procuring the coincidence of the chemical actinic and visual foci. The spherical aberration is also corrected very carefully, both in the central and oblique pencils.

One of the exhibitors of photographs, M. EVERARD BLANQUART, proposed the use of a white chamber, for accelerating the process; but there are serious objections to its adoption, and it therefore is not used.

The object-glasses exhibited are, for the most part, achromatic and double, and consist of two lenses placed at a distance from each other. A photographic object-glass without defect is yet a desideratum.

ROSS (No. 254, pp. 435, 436) has exhibited the best camera in the Exhibition. It is furnished with a double achromatic object-lens, about 3 inches aperture; there is no stop, and no part of the field employed which does not receive plenty of light; so that the corners as well as the middle of the picture are well illuminated. The field is flat, and the image is very perfect up to the edge. It has a revolving and adjusting back-board for the reception of two plates. The same exhibitor has a second camera, furnished with a single achromatic lens of small aperture. The glass of this instrument having been removed, the image could not be examined.

HENNEMAN and MALONE (No. 297, pp. 441, 442) exhibit a camera by ROSS. It is furnished with a single object-glass, aperture  $4\frac{1}{2}$  inches, the light is admitted through apertures 0.2 inch, 0.4 inch, 0.8 inch diameter, at about  $\frac{1}{2}$  inches, or at about one diameter of the lens from its surface, the combination being mounted on a brass cone attached to a mahogany plate, which slides and revolves on the front of the box, to allow any given point of the picture-plate to become the centre of the field. The

picture-board is  $8\frac{1}{2}$  by 10 inches; the focus varies from 10 inches to 17 inches according to the distance.

KNIGHT and SONS (No. 453, pp. 462, 463) exhibit a camera, the oak stand of which is solidly constructed and pretty firm. It has adjustments for height and azimuth, but not for angular altitude, and has no level. It is furnished with a double picture-plate. The box expands from  $9\frac{1}{2}$  to 14 inches. There is no lens, and consequently the image could not be examined. The same exhibitor has a second camera, in a neat, flat, folding mahogany box, with hinges, which closes up lengthways. It is on a slight, unstable tripod stand, made by cross bracings. The aperture of the object-glass (a single achromatic for landscapes) is about  $2\frac{1}{2}$  inches; the aperture in front of the glass is 0.6 inches, placed at  $3\frac{1}{2}$  inches in front of the lens. A projection placed in front of the aperture keeps off stray light. The lens is mounted on a slide to adjust to focus, and its focal length is about 12 inches. No ray can reach the corners of the picture when the lens is brought home, and only very little light when out as far as it will go.

HORNE, THORNTHWAITHE, and WOOD (No. 220, pp. 434, 435) exhibit a camera with a double achromatic object-glass, whose aperture is about  $2\frac{1}{2}$  inches. The size of the picture is 8 by 7 inches. The frame allows of two papers being placed in at one time. The box is made to fold together, and is a fine specimen of beautiful, neat, mahogany work, with many good contrivances to keep out light. There is no speciality in the construction of the daguerreotype and calotype apparatus of these exhibitors, excepting a mode of iodizing and bromizing the plates, by sliders of great neatness; the exquisite workmanship of their several articles; and the general arrangements for their use in daylight. Some very fine specimens of chemicals used in the process of photography are also exhibited. A Prize Medal was awarded to Messrs. HORNE and CO.

CLAUDET (No. 296, pp. 440, 441) has exhibited cameras; the largest has an aperture of 3 inches in diameter, double achromatic object-glass; when the whole aperture is open, about one-third of the breadth of the lens is cut off on either side, so that only about one-third of the breadth of the picture receives full light from the lens, and the illumination is in consequence very unequal. The image is good and the field is flat.

In Claudet's multiplying camera, the multiplying is performed by cross-sliding motions of the picture-plate, performed by two racks, working at right angles to each other, so as to present different parts of the picture-plate successively to the axis of the lens, exactness being secured by the division of the racks into inches and tenths of inches. The camera is short focussed, to give small miniature portraits, either presenting the same individual in different aspects, or several grouped together. The object-glass is double achromatic: its aperture is 3 inches, separated by 6 inches on a slide-rack to work in and out of the box; there are no diaphragms interposed. The front of the box carrying the object-glasses opens with a hinge. The tube projects one-eighth of an inch in front, outside of the object-glass, to cut off stray light. The focus is very short, having about 5 inches, extensible to about 8 inches by approach, within limits of motion. By focus is meant the distance of the picture-frame from the hinder surface of the hinder lens.

WILLATTS (No. 265, p. 437) exhibits a portable photographic camera with a flexible cloth body instead of a wooden one; it is furnished with horizontal movement, and is adjustable to lenses of various focal lengths; it has, also, an angular adjustment of the frame of the lenses, the latter for the purpose of keeping the image in the centre of the frame without altering the position of the camera. The size of the photographs is  $10\frac{1}{2}$  by  $8\frac{1}{2}$  inches. The cloth body of the instrument is mounted by flexible vulcanized caoutchouc bands at each extremity, and is thus firmly attached to the ends of the camera. The whole instrument is easily taken to pieces and put together, and occupies but a small space. The image was not examined.

WARLEY and SON (No. 257, p. 436) exhibit a single reflecting camera. This is a plain speculum with thin

edges, placed at an angle of  $45^\circ$ , and designed for making reversed copies of drawings on lithographic stone or wood blocks. It may also be fitted with lenses for enlarging or reducing copies, and for sketching from nature upon the stone. A Prize Medal was awarded to Messrs. Varley and Son.

ABRAHAM, ABRAHAM, and Co. (No. 266, p. 436) exhibit a portable sketching camera, furnished with a meniscus and prism in the place of a lens and mirror. When down, the size of the box is 15 inches in length, 8 in width, and  $3\frac{1}{4}$  in depth.

PLAGNIOL (France, No. 1679, p. 1257). This is by far the largest camera in the Exhibition; the picture-board is 24 inches square, and the object lens is 8 in diameter, double and achromatic. The picture was clear and distinct, as far as unfavourable circumstances would allow of the examination. It is furnished with a clear guard-tube in front of the object-glass, of 4 inches projection, amply sufficient to cut off side-light. The object-glasses are separated by 15 inches, or about double their aperture. The clear space which *all* the object-glass illumines, scarcely exceeds  $6\frac{1}{4}$  inches in the centre of the picture; at the edges and corners the defalcation of light is very great. This, however, seems to be unavoidable.

Large as is this camera, it is very far from being the largest that has been constructed. The use of great cameras for copying photographic plates and MSS., especially tables, is becoming common in France. We have heard of some cameras which give pictures nearly a metre in length. A Prize Medal was awarded to M. Plagniol.

SCHIERTZ (France, No. 999, p. 1227) exhibits a camera, the object-glass of which is  $2\frac{1}{2}$  inches in diameter. There is a stop, and the light is so effectually intercepted by the cell and tube of the second object-glass, that the sides of the field are rendered obscure, and the top, bottom, and corners *very* dark; not one-fifth of the central light is effective. The plate for receiving the image is 9 by 7 inches, and the focal distance from the hinder lens about 8 inches; the field is flat, and the image clear and good. The mahogany stand is good, but is not well adapted for taking panoramic views. A Prize Medal was awarded to M. Schiertz.

HARRISON (United States, No. 223, p. 1450) has exhibited two or three cameras, but as they are not mounted in boxes, and consist only of the brass-work and lenses, there were no means of trying their performance. They are constructed on the usual principle of double achromatic object-glasses, to give a flat field. The largest is about 4 inches aperture.

ALUSSE (Frankfort-on-Maine, No. 7, p. 1121) exhibits a camera, with a double achromatic object-glass,  $5\frac{1}{2}$  inches clear aperture: there is a slight stop placed between the two glasses, but it cuts off only the reflected light at the sides. The pictures produced are 14 by 11 inches; but the area fully illuminated is only  $4\frac{1}{2}$  inches in diameter, and the corners are very dark. With the full aperture the image in the centre of the field is somewhat imperfect; it will not bear magnifying, and sharp clear definition cannot be attained. Honourable Mention was awarded to Mr. Albert.

ROUGET DE L'ISLE (France, No. 1455, p. 1245). A camera-lucida for copying drawings, by reflection and vision at the same time, through a large vertically-placed sheet of plate glass. The drawing to be copied is laid horizontally on one side of the glass, and the paper to receive the copy on the other; the outlines are then traced by hand with freedom and facility, there being no necessity for using only one eye, or for fixing the position of the head. It is the simplest form of the camera-lucida. It inverts right and left; but this may be obviated, in some cases, by a looking-glass. The adjustments are easy and simple. Honourable Mention was awarded to M. Rouget de l'Isle.

#### Photographic Glass.

MESSRS. CHANCE and Co. (Class XXIV., No. 22, pp. 700, 701) have exhibited flint glass, in discs and in plates, adapted for the construction of object-glasses for Daguerreotype and Talbotype apparatus and cameras. Of these

discs one is as large as 20 inches in diameter, and there are some thin plates of the same kind of glass for cutting up.

The density of this glass is 3.20; the index of its refractive power is 1.60.

BURON (France, No. 443, p. 1199) has exhibited a collection of glasses of 6, 8, 10, and 12 inches diameter, for dissolving views.

#### Photography.

Rapid as have been the discoveries connected with Photography, and great as are the improvements it has received since the invention of M. Daguerre; there is yet much to be done to enable it to rank amongst the sciences of the age. It holds a place at present intermediate between an art and a science, a position eminently favourable to development in either direction. Its pursuit, as an elegant and most extensively useful art, affords a strong motive for inquiry and experiment in the improvement of its processes; in the course of which, an infinity of facts, new and unexpected, come forward, every one of which may turn out to be the embodiment of some pregnant scientific principle; nay, even the smallest minutiae of manipulation on which it is found that success or failure in the production of artistic effect depends, may, if duly observed and reasoned on, afford indications, linking together the known and the unknown in optical science, and tending to bring these mysterious operations of light within the pale of exact reasoning. On the other hand, science is too much in the habit of repaying to art, with interest, every assistance of that nature, to leave room for doubt of similar results in this instance, when once the principles of operative chemistry shall have assumed a definite form and subjective connexion. It is this which affords us full assurance that Photography is yet in its infancy, and that all which has been hitherto accomplished—marvellous and exquisite though it be, is as nothing to what will be performed when the veil shall be removed, which, for the present, obscures its true scientific principles. In this point of view the photographic study of the prismatic spectrum *per se*, apart from all artistic combinations and coloured media, cannot be too strongly recommended to experimenters, and we lament to observe only one instance, in the whole Exhibition (that of M. Claudet) in which this study appears to have been in any way followed up, so as to afford *exhibitable* results. Mr. Ross is understood, also, to construct the object-glasses of his photographic cameras, with especial reference to the excessive development of the actinic spectrum beyond the luminous one, in the direction of the violet rays. When bromine is used in the preparation of the plate or tablet, it may be questioned how far this is really an improvement? Should means be discovered of truly representing the colours of objects, and limiting the action to the luminous ray, the conditions of achromaticity for the photographic camera will be the same as for the telescope.

The fine collection of Photographs now exhibited will tend much to the advancement of this beautiful art, by showing us what has been done, and also by indicating that which it is necessary yet to do; and it will doubtless mark an era from which to date many improvements.

Since the epoch when M. Daguerre and Mr. Talbot first divulged their respective processes for impressing photographic images on silver and on paper, scientific men, both at home and abroad, have, by their increasing researches and improvements, brought Photography to a degree of perfection, which, however short of what it may one day acquire, yet seems incredible, considering its brief existence. Perhaps its advance cannot be more strongly proved than by the fact that the method, first adopted, but a few years since, for procuring daguerreotype portraits, required that a person should sit without moving for twenty-five minutes in a glaring sunshine. The improvement developed in the almost instantaneous process of the present day is most striking.

It is not the object of this report to trace the history of inventions, nor to decide on claims of priority, especially in relation to a subject which has received accessions from such innumerable quarters, and called into action

the skill of so many eminent chemists and photologists of every nation. Suffice it to say, that, after the introduction of M. Claudet's accelerating process by the application of chloride of iodine and chloride of bromine (an invention which he liberally gave to the public through the medium of the Royal Society and the Académie des Sciences); the Daguerreotype process, as publicly practised, became reduced to some system, and two Daguerreotype establishments were formed in London. The portraits taken, at this time, were, however, deficient in expression; but in spite of all deficiencies, the receipts of these establishments several times amounted to 60*l.* in one day.

At a somewhat later period that remarkable variety of the Talbotype process, designated by its inventor by the name of "Kalotype" was also publicly employed for the production of portraits by Mr. Collier: the artistic effect in these representations was susceptible of being much heightened by the brush and the defects of expression might be removed, and the likeness in consequence greatly improved by one or more subsequent sittings.

M. Claudet, who, from the earliest time of the Daguerrian invention, displayed great genius and ability in perfecting the various processes, first perceived the necessity of aiding the artistic effect of his representations by subsidiary adjuncts of a different kind. He it was who first practised the placing of painted back-grounds behind the persons whose portraits were to be taken. Thus an infinite variety of scene might be afforded by the operator simply providing himself with a few subjects skilfully adapted to the requirements of the occasion. To him also we owe that extremely pleasing adaptation of mechanical adjustments for bringing many miniature representations of the same individual under different aspects, to be impressed in regular compartments of the same plate and framed together,—of which we find specimens exhibited in his collection.

It is not necessary to detail, step by step, the successive improvements in the different processes and apparatus for Daguerreotypic Photography, though we may mention that to the exertions of Messrs. Claudet, Gaudin, Fizeau, and Draper, the public are indebted for many improvements. To M. Fizeau is due the reproduction of the proofs of electrotype; also a new process for engraving the Daguerrian image, and of preserving that image from destruction by gilding the surface.

The Exhibition presents many fine calotypes, or as they are sometimes called in the Catalogue "sun-pictures," for the production of which the preparations of Mr. TALBOT hold the first rank. M. BAYARD, also, has been celebrated for his achievements in this line, and has contributed many splendid proofs, obtained on various sensitive papers. Mr. Talbot has, himself, exhibited nothing; but many of his productions will be recognized among those exhibited by HENNEMAN and MALONE, as adapted to the practical wants of travellers, collectors, &c. This branch of the art offers inestimable advantages, viz.: 1st, That the papers may be prepared at leisure, some time before an occasion for using them arrives; 2ndly, That when pressed and fixed, they may be carried without injury in a portfolio, like other drawings; 3rdly, That from one good negative original, any number of positive copies may be taken, to the extent, indeed, of two or three hundred copies in a rainy day, as proved by the practice of M. EVERARD BLANQUART (Prince, No. 1551), and supplied to the public at a cheap rate; 4thly, That they may be wholly obliterated so as to reduce them apparently to the original condition of white paper, and carried about in that state for an indefinite period, though susceptible of revival at any instant. Considering it probable that the following communication, addressed by M. Arago to the Academy of Sciences, on the granting a national recompense to M. Daguerre, may be as useful to a portion of the public, now, as then; we subjoin it in the words of M. Arago himself:—

"A short time after the law was voted, granting a national recompense to M. Daguerre, some opinions, which in my idea were very erroneous, were entertained by a small portion of the public, which rendered it necessary for me to show that the discovery, newly made, was not to be estimated in respect to art only, but to the very

valuable subjects for investigation which it presented in reference to the physical sciences."

Without further remark, we proceed to the discussion of the Photographs exhibited.

#### *Daguerreotype Pictures.*

CLAUDET (No. 296, pp. 440, 441) has exhibited a large collection of daguerreotype portraits, both plain and coloured. Amongst various excellences of which they are possessed, we may particularly mention that of their *non-inverting*. This is a great improvement, and by it M. Claudet has annulled the superiority which the sun-pictures have so long possessed, in this particular, over the daguerreotypes.

On examining the uncoloured specimens exhibited by Claudet, it will be found that they are distinguished by artistic arrangement, judicious distribution of light and shade, and great clearness of definition. The general tone is good,—M. Claudet having uniformly avoided violent contrasts of light and shade; a circumstance to which much of his success may be attributed. In this collection are several female portraits in white draperies, which pictures deserve commendation for their beauty of detail and freedom from solarization. Many of the above remarks apply, equally, to the coloured specimens, most of which are portraits, and are distinguished by careful and harmonious colouring, the focus having been so judiciously selected, and most of them present an artistic and natural appearance, seldom hitherto obtained by Daguerreotypists.

Photography may be said to be too faithfully exact in its results, for the purposes of art; detailing, as it does, the accessories in the back ground and the main object of the group with equal fidelity. When blending colour with photographic works, or in visibly uniting art and science on the same plate, the operator should be possessed of knowledge and feeling sufficient to know the proportions in which art and science should intermingle so as to be subservient to each other: in this knowledge, which is chiefly dependent upon the proper focal adjustments of the picture, M. Claudet excels; and the admirable manner in which he sacrifices the details, afforded him by science, to the requirements of his subject, is the result of long and laborious investigation.

An uncoloured daguerreotype by Claudet is worthy of particular mention; it represents various articles of vertu, pictures, &c., grouped together: the perfect focus of each part and general relief of the whole prove it to be a successful application of his focimeter.

M. Claudet also exhibits the dynactimometer\* and focimeter. He also exhibits the effects of the spectrum on the daguerreotype plate, as prepared by him, and a variety of curious and instructive specimens illustrative of the different refrangible rays. The Council Medal was awarded to M. Claudet.

KILBURN (No. 294, p. 440) has exhibited a case containing several carefully-selected specimens of coloured daguerreotypes. The subjects of these pictures are confined to groups of figures of small size, and are very brilliant and elaborate in their details,—too much so for artistic effect. For novelty of design we may mention a small picture of the interior of a room, including a whole-length portrait of Jenny Lind: beside, and near her, is a large mirror, in which the figure is reflected. That the reflection in the glass is equally perfect with the original is the point worthy of remark and commendation. Towards the centre of this case is a plain daguerreotype portrait of the Queen. The finish and execution of this little work are very great. The Jury awarded a Prize Medal to Mr. Kilburn.

MAYALL (No. 291, pp. 439, 440) has exhibited in this department a large collection of daguerreotypes, uncoloured. They are characterized by great contrasts of

\* The reader is referred for an account of the dynactimometer to the "Reports of the British Association," August 1850, and to the "Philosophical Magazine," June 1851, and for the focimeter, to the "British Association Reports," September 1849, and "Philosophical Magazine," November 1849.

light and shade, disposed in large masses. Among the subjects exhibited are four tableaux from the "Soldier's Dream," and several groups from Nature, variously arranged. Mr. Mayall's strong and broad masses of light and shade are better adapted for landscape scenery, of which the "Falls of Niagara" is a favourable specimen. His "Bacchus and Ariadne," 24 in. by 15 in., is, perhaps, the largest *daguerreotype* which has yet been executed. The difficulty of duly preparing so great a surface must be extreme. He has also exhibited a crayon *daguerreotype*, produced by a process of his own invention.\*

BEARD (No. 292, p. 440) has exhibited a case of *daguerreotypes*, some of them enamelled, according to a process invented by himself.†

LAROCHE (Class XXX., No. 252, p. 837) has exhibited three small *daguerreotypes*: two are coloured: the third, a group of statuary, is good.

VOIGTLANDER and EVANS (Class XXX., No. 254, p. 837), Knightsbridge, have exhibited coloured *daguerreotypes*.

Of the remaining exhibitors in England,—GRIFFITHS and LE BEAU (No. 404, p. 453) have exhibited a case of *daguerreotype* miniatures, coloured. PAINE (No. 295, p. 440), a series of photographic pictures, intended to show the processes of the art. TYLER (No. 293, p. 442), coloured *daguerreotype* portraits; and CRADDOCK (Class XXX., No. 227, p. 834), photographic copies of various engravings.

On examining the *daguerreotypes* contributed by the United States, every observer must be struck with their beauty of execution, the broad and well-toned masses of light and shade, and the total absence of all glare, which render them so superior to many works of this class. Were we to particularize the individual excellences of the pictures exhibited, we should far exceed the limits of space to which we are necessarily confined. Where all is good, it follows that remarks must be restricted to peculiar excellence alone.

Before speaking of the several works exhibited, it is but fair to our own photographers to observe, that much as America has produced, and excellent as are her works, every effort has been seconded by all that climate and the purest of atmospheres could effect; and when we consider how important an element of the process is a clear atmosphere, we must be careful not to overrate that superiority of execution which America certainly manifests.

LAWRENCE, of New York (United States, No. 151, p. 1446), has exhibited several *daguerreotype* portraits, uncoloured. They are remarkable for clear definition and general excellence of execution. In this series two large portraits of General J. Watson and W. Bryant, Esq., each of which measures 12½ in. by 10½ in., deserve particular commendation. Notwithstanding their large size, they are, throughout, perfectly in focus, and are beautifully finished in all their details. These are two of the best pictures in the American collection. A portrait of General J. W. Wells, and of a lady in a black silk dress, of a smaller size, are also remarkable. A Council Medal was awarded to Mr. Lawrence by the Jury, but not confirmed by the Group.

BRADY (United States, No. 137, p. 1441) has exhibited forty-eight *daguerreotypes*, uncoloured. These are excellent for beauty of execution. The portraits stand forward in bold relief, upon a plain background. The artist having placed implicit reliance upon his knowledge of photographic science, has neglected to avail himself of the resources of art. The portraits of General Taylor, Calhoun, General Cass, and James Perry, are strikingly excellent; but all are so good that selection is almost impossible. The Jury awarded the Prize Medal to Mr. Brady.

WHIPPLE (United States, No. 451, p. 1464) has exhibited several specimens of *daguerreotypes*, amongst which one of the moon may be mentioned with the highest commendation: this is, perhaps, one of the most satis-

factory attempts that has yet been made to realise, by a photographic process, the telescopic appearance of a heavenly body, and must be regarded as indicating the commencement of a new era in astronomical representation. The same exhibitor has included in his collection three pictures, containing several full-length figures, well grouped, and artistically arranged. Each part is well in focus, and the definition is admirable. An agreeable tone pervades all these pictures. A Prize Medal was awarded to Mr. Whipple.

MAYALL (United States, No. 491, p. 1465) has contributed largely to the American collection,—his works here being characterized by the same broad masses of light and shadow as those which he has exhibited in the British Department (No. 291). The subjects of the pictures in the present series consist chiefly of small groups and portraits; also two cases containing illustrations of the Lord's Prayer. The majority of these (most of which are uncoloured) are effective, verging upon the theatrical in point of style, but they are not all equally well defined. We should be doing Mr. Mayall an injustice, were we not to mention, as a brilliant exception to the above criticism, a small figure of a female reclining; it is exquisite in delicacy of execution, harmonious distribution of light and shade, whilst an admirable tone pervades the whole picture; this, the finest of Mr. Mayall's contributions, is free from colour, and is *daguerreotyped* from a classic work of art. The Jury awarded Honourable Mention to this exhibitor.

EVANS, New York (United States, No. 105, p. 1440), has exhibited several portraits of great merit. Those of the Rev. — Jagersoll, Dr. Nott, Dr. Lord, and Dr. Shelton, are characterized by peculiar excellence; also two portraits, each of a lady sitting near a table upon which a group of flowers is displayed, deserve to be noticed as fair specimens of the perfection to which this application of science, to the purposes of art, has been carried.

MEADE BROTHERS (United States, No. 109, p. 1440) have exhibited a series of portraits of more than ordinary size. Conspicuous among this collection are the heads of Wallack and H. W. Meade. The modulation of light and shade upon these last is admirable, as well as the details of the features, and the total absence of all harshness: the artistic effect is excellent. Greater credit is due to this collection of portraits, than to the series of allegorical subjects exhibited by Mr. Meade.

PRATT, RICHMOND, and Co. (United States, No. 264, p. 1452), have exhibited several *daguerreotypes*, of various degrees of excellence. The profile of an old man, assisted by colour, is the best.

WHITEHURST, Virginia (United States, No. 377, p. 1461), has exhibited twelve views of the Falls of Niagara. These are admirable, and possess a degree of reality not always attained in landscapes produced by the *daguerreotype* process.

Among the remaining exhibitors of *daguerreotypes* in the United States Department are—

GAUIT (United States, No. 125, p. 1411), Root (United States, No. 42, p. 1435), WHITEHURST (United States, No. 525, p. 1467), and HOGG (United States), all of whom have exhibited *daguerreotypes*, but not distinguished by any striking degree of excellence. LANGENHEIM (United States, No. 62, p. 1437) has exhibited two large Talbotypes, one of which is a panoramic view of Philadelphia, executed in compartments, but wanting unity of effect. This artist, also, exhibits a series of subjects on glass, designated by him under the name of hyalotypes, being delicate miniatures, excellently adapted for magic-lantern subjects. The material would appear to be collodion, albumen, or some similar preparation, forming a film on the glass, capable of receiving the impression. A *daguerreotype* view of Cincinnati, by FONTYNE and PORTER (United States, No. 550, p. 1468), is more successful. This is also taken in separate compartments: it is clear and good in colour, and forms an effective picture. HARRISON (United States, No. 223, p. 1450) has also some *daguerreotypes* of a very superior description.

In turning our attention to France, we find several *daguerreotypes*, which, in contradistinction to those of America, are characterized by large masses of light, in

\* See the Illustrated Catalogue, and the Athenæum for 1850, p. 1018.

† See the Illustrated Catalogue, note ii. p. 428.

which is expressed the greater amount of detail and minutiae. They are not so entirely free from glare as those of America.

THIERRY (France, No. 1038, p. 1228), has exhibited eight daguerreotype views of Lyons; they have a sunny look, and are very brilliant, but are wanting in artistic effects of light and shade. A portrait of M. Thierry himself deserves particular commendation, and is far superior to the above-mentioned pictures. The Jury considered this exhibitor as deserving Honourable Mention.

MAUCOUBLE (France, No. 620, p. 1207) has exhibited a case of very highly-coloured daguerreotype portraits. These are excellent, but possibly belong more to the fine arts than to photographic science. It is difficult to say whether the harmonious and rich colouring of the French school, as applied to these portraits, or the masterly blending of the colour and daguerreotype, deserve the most commendation. Art is here engrafted on science, the latter being merged in the former, and the impression left on the mind is that naturally produced by the view of a beautiful artistic production. They are charming, but we repeat belong more to art than to science. The Jury have awarded these works Honourable Mention.

SABATIER (France, No. 1467, p. 1246) exhibits a single daguerreotype portrait of large size (8 in. by 6 in.), which is every way excellent. It is entirely free from glare (to which its low position contributes not a little, the light coming from above), and in expression, freedom from constraint, and perfect representation of texture, may rank with any single piece in the Exhibition.

PLAIGNOL (France, No. 1679, p. 1257) exhibits daguerreotypes rather as specimens of the production of his large camera (though not of the full size which that instrument is capable of producing), than as claiming especial distinction in this particular department of art.

GOUIN (France, No. 241, p. 1188) exhibits a series of coloured daguerreotypes, which, however, want brilliancy and purity of colour; the back grounds are also out of focus. An uncoloured portrait, 7½ in. by 6 in., does better justice to the powers of this exhibitor.

KOHNE (Hamburg, No. 103, p. 1140), and VON MIKUTOL (Prussia, No. 191, p. 1058), have exhibited daguerreotypes.

VOGEL (Austria, No. 739, p. 1044) exhibits daguerreotypes, to which Honourable Mention was awarded by the Jury.

#### *Talbotypes - Calotypes - Sun-pictures.*

BUCKLE (Class XXX., No. 301, p. 840), of Peterborough, has exhibited a great many calotype pictures, all of which are characterized by great delicacy of tint and exquisite cleanness of execution, and deserve to be ranked among the finest specimens of photography in the Exhibition. The process adopted by Mr. Buckle, he has described at some length; it is not subjoined here, from want of sufficient space, but the beauty of Mr. Buckle's calotypes sufficiently testifies to the superiority of his method. He observes that, with regard to the adjustment of the focus, no rule can be laid down; but, having himself a knowledge of art, practical as well as theoretical, he applies it to the arrangement of the subject and to deciding on that point of the picture best calculated to be put into focus. The size of the aperture of the lens, as also, the time of exposure, are so much matters to be decided on at the time of taking the picture, as to render the laying down any fixed rule next to impossible. The paper employed, Mr. Buckle observes, is made by Mr. Turner, of Chafford Mills, and is, he considers, unequalled. Mr. Buckle's negative originals, it should also be observed, are on paper. He does not employ the albuminous process. A Council Medal was awarded to Mr. Buckle.

ROSS and THOMSON (Class XXX., No. 299, p. 839) have exhibited several beautiful Talbotype pictures, consisting of views from nature, interiors, groups, &c., and they are the only exhibitors, in the British section, of photographs by the albuminous process; which, in practice, they appear to have carried to a high state of perfection, having not only substituted it for the old method of

taking the negative proofs on paper, but having, in more than one instance, exhibited the positive proof upon the albumenized glass itself. In addition to the extreme clearness observable in the details of their landscape scenery, and the great delicacy of their delineation of objects in general, we may take notice of the excessive beauty of the tints which their works exhibit. Not only are the shadows deep and Rembrandt-looking, where suitable to the effect required, but the middle distances display a beauty of colour nowhere equalled, excepting in the very superior works by M. Martens, in the French Department.

As an illustration of the variation of tints which these works present, in contradistinction to the fine Vandyke brown and deep shadows, we may mention a small picture (a group of statuary), the peculiarity of which consists in the colour, which is blue, an effect produced by taking the negative proof on albumenized glass, and rendering it positive by repeated washing in hyposulphate of soda, the proof being originally laid upon a black ground. By this process the whites become black, and *vice versa*. The hyposulphate of soda is a most useful agent in the colouring of both negative and positive proofs, and affords a vast range of beautiful tints of inexhaustible richness; but it is difficult of application, and is available only in the hands of a skilful operator.

The coating of the glass with albumen is a difficult operation; the method adopted by Ross and Thomson differs from the French process (which is due to M. Niepce, and is usually called the "albuminous process"); and consists in pouring a quantity of albumen on the plate and revolving it over a slow heat, for the purpose of ensuring its even distribution. As shown in the practice of these exhibitors, this method would seem to be perfectly successful; and indeed the beautiful and extreme delicacy and variety of tint, the aerial perspective by which the background is made to recede by imperceptible gradations into the horizon, all amply attest the powers of Messrs. Ross and Thomson.

A number of Talbotypes, also exhibited, display equal variety of tint, and a depth and richness of tone without any straining for effect.

A Council Medal was awarded to Messrs. Ross and Thomson.

HILL and ADAMSON (Class XXX., No. 300, p. 839) have exhibited very many Talbotype groups, remarkable for easy and graceful arrangement. They are, in effect, after Rembrandt, being made out in broad and deep-toned masses of light and shade. As a whole, they are very sketchy and spirited. The tints are rich and varied both in depth and colour, and are of a rich sepia. They have received Honourable Mention from the Jury.

HENNEMAN and MALONE (No. 297, pp. 441, 442) have exhibited Talbotypes on paper, consisting of copies of small intaglios, portraits, both plain and coloured, and various small groups, &c. These are all natural and pleasing, and great delicacy is observable in the lights and shades, the tone of which is a fine warm sepia brown. The greater part of these pictures are small portraits; one, however, which is 8 in. by 6½ in., is very good, and evenly illuminated. The coloured portraits in this collection are very good, and no little credit is due to the artistic skill which they display.

Messrs. Henneman and Malone also exhibit specimens of the cyanotype and chrysotype processes of Sir J. Herschel, the chromotype of Mr. Hunt, and Talbotypes tinted by the application of caustic potash and a lead salt. A Prize Medal was awarded by the Jury to Messrs. Henneman and Malone.

COLLS, R. and L. (No. 303, p. 442), have exhibited several sun-pictures on paper. They are rather blotty in appearance, but are good in colour. Views of Windsor Castle and Stoke Church deserve high commendation.

HARMER (Class XXX., No. 298, p. 839) has exhibited two calotype pictures, one a landscape; the reflections as shown in the water are excellent. The fluctuation of the reflections caused by the ripple of the water is very beautiful, and true to nature. The execution of the picture is good, and the tints are clear and delicate.

QWEN (No. 670, p. 467\*), of Bristol, has exhibited a

series of calotype pictures, most of them landscapes and wood scenery. They want clearness of definition, being somewhat black and heavy. Mr. Owen states himself to have been able to execute in a single day, in a journey of 300 miles, ten large-sized Talbotype pictures of local scenery, each paper being prepared on the spot. The preparation is greatly facilitated by a glass spreader, of his own invention, by which the solutions are evenly applied.

COLLIE (No. 22, pp. 941, 942), of Jersey, has exhibited a frame, containing several calotype pictures, chiefly portraits and domestic scenes. These are not all equally good; many of them are blotty and wanting in depth.

RIPPINGHAM (Class X., No. 304, p. 442) has exhibited several Talbotypes, being a series of untouched positives, from collodion negatives, on plate glass. He also exhibits other photographs from paper negatives, but they are blotty and want more light.

BINGHAM (Class X., No. 302, p. 442) is an exhibitor of Talbotype pictures, landscapes chiefly. Being near objects, such as cottages, trees, &c., there is no room for aerial perspective. They are very cleanly executed.

FIELD and SON (No. 250, p. 435) have exhibited calotypes.

MARTENS (France, No. 610, p. 1207) has contributed several large and beautiful photographic proofs, on glass and paper, obtained by an apparatus made by Leicbours and Secretan; also several large photographs from negatives on glass, five of which (views of "Notre Dame," the "Louvre," and "St. Germain-de-l'Auxerrois"), measure 12 in. by 9½ in., and are pre-eminently beautiful. Two pieces of sculpture, from the "Arche de Triomphe, Barrière de l'Etoile," call forth the highest admiration. One of these groups contains seven full-length figures, together with their accoutrements, in a space of 3½ in. by 3 in.; the great finish and beauty of execution here displayed have never been excelled. Space does not permit us to individualize all M. Martens' works, most of which are equally good, such as the "Ceiling of the Louvre," the "Château de Vincennes," &c.; but we may say that, for richness of effect and perfection of definition, they are the finest specimens which it seems possible to produce, exhibiting as they do a most successful combination of careful execution, delicacy of colour, and great artistic merit. No trace of the brush is visible. A daguerreotype view of Paris, by the same exhibitor, is good, and evidently not retouched. A Council Medal was awarded to M. Martens.

BAYARD (France, No. 414, p. 1198) has exhibited several sun-pictures, the subjects of which are chiefly selected portions from the public buildings of Paris. One of the cases exhibited by M. Bayard contains five pictures, all excellent; though to the "Bibliothèque de Louvre" we may give the preference for its judicious arrangement of light and shade and elaborate representation of detail. The interior of a church is deserving of separate mention; the figures, which are numerous, are admirable, and their perfect delineation, even when remote from the eye and in deep shadow, is worthy of commendation. Also a calotype of "Venus and Cupid," from a bas-relief, is worthy of mention, owing to the beautiful tint which pervades the picture. In M. Bayard's representations of sculpture, the difference of surface and texture between the plaster cast and marble statue is marked with perfect distinctness. A Prize Medal was awarded to M. Bayard.

FLACHERON-HAYARD (France, No. 836, p. 1220) has exhibited several sun-pictures of ruins in Spain, Rome, and Paris. These are all excellent; the colour is good, and the artistic effect admirable. They appear to be possessed of nearly equal merit. The "Arch of Titus" deserves especial mention for the perfectly artistic expression of the whole, combined with a singularly accurate representation of the superficial texture of the material. A Prize Medal was awarded to M. Flacheron.

LE GRAY (France, No. 585, p. 1206) has exhibited several sun-pictures. Some of these are good, but many are heavy and wanting in detail. These pictures vary, in tint, from sepia to olive citrine.

HENRI LE SECQ (France, No. 592, p. 1206) has exhibited several calotypes; the subjects are architectural.

These pictures may be mentioned with great commendation as regards their photographic finish; but nearly all of them exhibit a degree of negligence in adjusting the visual axis of the camera to the true horizontal direction, which, by making all the vertical lines of the buildings *visibly convergent* in the picture, contravenes the rules of perspective, and produces an effect highly displeasing. This is the most common fault of photographic representation by the aid of a camera, and it is right to notice it to put artists on their guard. Every photographic camera ought to be provided with a small spirit-level to secure this adjustment in the field, independent of trial.

EVARD, BLANQUART (France, No. 1551, p. 1251) has exhibited several Talbotype pictures, the positive proofs being obtained by a process which admits of 200 or 300 impressions being taken from the same negative proof; the price varying from five to fifteen centimes, according to the size. These are not wholly successful; several of the pictures are dark and blotty, and somewhat resemble engravings taken from a worn-out plate.

COUSIN (France, No. 1572, p. 1252) exhibits a series of positive Talbotypes, from negatives on paper, in all seven subjects, six of which are of exquisite beauty.

ALBERT (Frankfort-on-the-Maine, No. 7, p. 1121) has exhibited sun-pictures of large size, but they are "fuzzy," being ill-defined and void of effect. Two specimens of smaller size, one of them coloured, are good.

CHEVALIER (France, No. 1729, p. 1259) exhibits some photographic proofs.

MAYER (France, No. 622, p. 1207) has a series of miniatures, coloured on Talbotype grounds. They are of exquisite beauty, and give the idea of perfect likenesses; but the use of the brush being obvious, they are rather to be regarded as works of art than of science.

PRETSCH (Austria, No. 362, p. 1027) has exhibited several large photographic pictures from nature. The subjects are various, comprising groups of statuary, architectural buildings, landscapes, &c. The subjects are well chosen, and show good execution and artistic management. Mr. Pretsch was awarded the Prize Medal by the Jury.

In closing our remarks on this department of the Exhibition, we may be permitted to record some degree of disappointment at the absence of specimens of the application of photography to any departments of representation, other than such as please the eye or administer to personal feelings. As regards its application to an infinity of useful and instructive purposes, we have literally nothing! We find, for instance, no specimens of copies of ancient inscriptions (a few incidentally occurring on the Roman ruins, perfectly familiar to every one, only excepted)—no delineations of tropical or remote scenery—no specimens (for the single exception of Claudet's spectrum is hardly to be cited) of the actinic spectrum on chemical preparations, or on natural vegetables or animal colours,—no impressions of the lines in the photographic corresponding to those in the luminous spectrum,—no magnified representations of the microscopic products of nature, or of the dissected parts of plants or animals,—no copies of pages of ancient manuscripts,—no miniatures of printed books (holding out the promise of future publications in miniature), or that of condensing in volume for preservation in Museums,\* &c., the enormous mass of documentary matter which daily more and more defies collection from the mere impossibility of stowage, but which will one day become matter of history,—and a thousand other applications that it would be tedious here to mention.

Connected with photography, we may also notice the absence of any specimens of scotography, or the art of copying engravings by simple juxtaposition in the dark by obscure inter-radiation, invented by Moser.

#### • • Magnets.

Exhibitors of magnets are few in number; among them LOGEMAN (Netherlands, No. 87, p. 1147) and HENLEY

\* We are informed that a catalogue of the National Library of Paris, in which the photographic fac-simile of the title-page of each work, in miniature, is registered, is actually in progress.

(England, No. 428, pp. 457, 458) have exhibited the most powerful steel magnets; it is satisfactory to learn that both these exhibitors are still applying themselves to their further improvement.

HEARDER (No. 439, p. 461) deserves special notice for the attention he has devoted to ascertaining the receptive and permanent magnetic powers of cast iron, both in separate plates and in their combinations.

As early as the year 1832, Dr. Scoresby commenced a series of experiments on the magnetic properties of cast iron, but which, owing to the thickness of the masses employed, did not yield decisive results; prior to the year 1844, he repeated his experiments upon different kinds of cast iron, and found that "cast iron possesses considerable powers of magnetism, both in capacity and retentiveness, though greatly inferior in both qualities to those of properly-hardened steel;" with several other interesting results.\* The general results arrived at by Dr. Scoresby, though calculated to show the unsuitable character of the specimens and forms of the cast iron employed by him to general magnetic purposes, were yet of such an encouraging nature, as to lead to the hope that more important results might be obtained by the employment of cast iron in large masses, and in different forms.

Mr. Hearder was led, in the course of his experiments, to consider that cast iron had not been subjected to a sufficient variety of tests, and he was still more confirmed in this opinion, by observing how its mechanical properties varied, according to the temperature of the different kinds of iron, and he concluded that the conditions which acted against its being used as a bar magnet might be made available for one of the horse-shoe form. In 1843, he made the magnet now in the Exhibition, which is still possessed of considerable power, as determined by the Jury.†

The following are the particulars of the magnets exhibited:—

LOGEMAN (Netherlands, No. 87, p. 147) has exhibited the most powerful permanent magnets in the Exhibition.

The following are the results of the experiments:—

One whose weight was 1 lb.  $\frac{1}{2}$  oz. carried a weight of 16 lbs.  $9\frac{1}{2}$  oz.

One whose weight was 6 lbs.  $\frac{1}{2}$  oz. carried a weight of 66 lbs.  $3\frac{1}{2}$  oz.

One whose weight was 101 lbs. 12 oz. carried a weight of 436 lbs. 12 oz.

A Council Medal was awarded to Mr. Logeman.

The exhibitor of the next best magnets was HENLEY (No. 428, pp. 457, 458), and the results of the experiments are as follows:—

A magnet weighing 2 lbs. 5 oz. carried a weight of 31 lbs.  $5\frac{1}{2}$  oz.

A magnet weighing 8 lbs. 4 oz. carried a weight of 56 lbs. 14 oz.

A magnet weighing 32 lbs. 6 oz. carried a weight of 120 lbs.  $4\frac{1}{2}$  oz.

SHAW and SON, Sheffield (Class XXII., No. 216, p. 617), exhibited several magnets:—

One whose weight was 7 oz. carried 4 lbs., and

One whose weight was 7 lbs.  $\frac{3}{4}$  oz. carried 61 lbs.  $7\frac{1}{2}$  oz.

HEARDER (No. 439, p. 461) has exhibited a cast-iron compound horse-shoe permanent magnet. This magnet was constructed with a view to its being applicable to every purpose requiring high magnetic power.‡ It consists of 24 plates, 2 inches wide and 0.19 inch thick, cast in the form of a horse-shoe, which is 16.75 inches in length. The 24 plates are strongly fastened together; the poles, which are distant from each other 1.25 inches, are capped with soft iron, for the purpose of concentrating

the magnetic power; at the same time it renders the grinding of the poles unnecessary.

The construction is simple. The bars being made of iron, hardened as much as possible, require no preparation to adapt them for magnetization.

The economy of construction, as compared with a steel magnet of the same dimensions, is estimated as 4 to 1.

It is designed to be made available for the construction of electric machines for telegraphic or electro-chemical purposes, and was manufactured at Mr. Hearder's establishment at Plymouth.

Mr. Hearder observes that, whatever be the relative powers of the plates previously to their being put together, as a mass they are found to undergo a considerable change; the two external magnets having their poles slightly reversed, the two next being neutral, and the rest having direct polarity, being strongest in the centre, and gradually diminishing towards the two external plates. On testing the individual powers of each magnet, after their several combinations, for three years, the sum of the whole was less than 15 lbs., whilst collectively they were capable of lifting a weight of more than 100 lbs.

Other particulars concerning this magnet are to be found in the Report of the Royal Cornwall Polytechnic Institution for 1850.

This magnet was found to weigh 71 lbs. 8 oz., and to carry a weight of 120 lbs. 9 oz.

Mr. Hearder has exhibited a powerful horse-shoe permanent steel magnet, intended for all purposes requiring high magnetic power.

It is composed of a large number of wide and extremely thin horse-shoe plates, cut out of thin sheet steel, tempered and hardened sufficiently to admit of their being flattened with a hammer. The magnet weighs 39 lbs., and Mr. Hearder says will support nearly 250 lbs., with a round-faced keeper. It is intended for magneto-electric purposes, where great power is required in a small space. This magnet was found to weigh 39 lbs., and to carry a weight of 112 lbs. 9 oz.

KUNDELL (No. 438A, p. 461) exhibits a carbonized cast-iron magnet; the carbonization having been performed by prussiate of potash and oil. This magnet is offered as an improvement on Mr. Hearder's cast-iron magnet, as shown at the last Polytechnic Exhibition. On trial, this magnet was found to weigh 27 lbs. 8 oz., and to carry 35 lbs. 9 oz.

#### *Magnetical Instruments.*

BROOKE (No. 144, pp. 422—426) exhibits photographic apparatus for the self-registration of the changes of position of the declination magnet, of the horizontal force magnet, and of the vertical force magnet.

The three magnets are so placed, that the residual effect of each pair upon the third is a minimum, which is to be determined by experiment.

The principle is the same for all, viz., wrapping prepared photographic paper around a cylinder whose axis is placed parallel to the direction of movement to be registered, and which is turned round uniformly by clockwork.

The light, from a gas-lamp, passes through a small aperture placed near it, and falls upon a concave mirror of speculum metal, which rests in a stirrup firmly connected to the magnet, so that it partakes of all the angular movements of the magnet. The pencil of light is then deflected from the mirror to a plano-convex lens, placed parallel to the axis of the cylinder, and near to it: this lens condenses the line of light to a definite spot of light on the paper. This spot of light, therefore, moves with the movements to be registered,—to the right and left, in a horizontal plane, in the case of the declination magnet and horizontal force magnet; and up and down, in a vertical plane, to register the movement of the vertical force magnet; the cylinder, as before stated, being turned round by clockwork. Consequently, there is traced upon the paper a curve, of which the abscissa, measured in the direction of a line round the cylinder, is proportional to the time, while the ordinate, measured in the direction of the axis of the cylinder, is proportional to the movement of the magnet.

A base line, or a line from which to measure the ordi-

\* See Scoresby's "Magnetical Investigations," Part II., Chap. viii., pp. 310-317.

† It was described in the "Electrical Magazine," October, 1845, vol. ii., p. 137.

‡ These magnets are termed "permanent," in contradistinction to the temporary electro-magnets.

uates, is traced upon the paper by the action of a spot of light proceeding from another gas-lamp placed near the cylinder, and passing through a slit fixed to the carrier of the cylinder.

To the horizontal force magnet there are attached apparatus for correction of temperature.

That for the horizontal force magnet, which is described in the Illustrated Catalogue, page 411 (Second Part), is based upon the following consideration:—

Let ( $b$ ) be the lower interval between the two divisions of the suspension skein, the equation of equilibrium being—

$$mX = \frac{ah}{b} \sin \theta;$$

then the arrangement adopted is to make the variation of  $b$ , by the effect of temperature, equal to the variation of  $m$ , arising from the same cause. This is attempted to be effected by clamping to the magnet a glass rod, the ends of which are inclosed in two zinc tubes, whose adjacent ends are separated by the width of the clamp. The zinc tubes and glass rod are clamped together at such a distance from the centre of suspension, that the ratio of the difference of linear expansion of the length of glass and zinc, intervening between the clamps to the interval ( $b$ ), may be equal to the temperature coefficient.

The clamps are adjusted in order that, when their position has been approximately determined by calculation, the error of position may be corrected by experiment.

As the expansion of glass and zinc are both taken to be uniform, and are at any rate far beyond the limits of atmospheric change, this method cannot serve to represent the coefficient of ( $t$ ), and the residual error of the corrected instrument must be experimentally determined.\*

The arrangement for the correction of the vertical force magnet is made by clamping a small thermometer to the magnet, parallel to its axis, and in the same plane as the knife-edges. The middle point between the freezing point of the thermometer and the centre of the ball is placed opposite the centre of the magnet.

Let  $w$  be the weight that at a distance  $q$  from the line of suspension would be equivalent to the temperature correction for  $1^\circ$  Fahrenheit, or  $32^\circ$ ;  $\pi$  the weight of mercury contained in one degree of the scale of the thermometer;  $p$  the distance of the freezing point from the centre of the ball, and  $2\pi$  the length of one degree of the scale; also let  $cx + \pi x^2$  be the temperature coefficient of the magnet; then if

$$Q = pw, \text{ and } c : \pi :: p : \pi.$$

The statical moment of the mercury displaced from the ball at any temperature  $x^\circ$  above  $32^\circ$ , will be equivalent to  $cx + \pi x^2$ , and will represent the temperature correction.

We will now proceed to detail the process of preparing the paper, bringing out and fixing the photographic impression.

The paper used should be of a strong even texture, and prepared with attention, to the exclusion of all foreign substances which might combine injuriously with the chemicals used.

The first preparation of the paper is with—

Isinglass 4 grains.

Distilled water 1 fluid ounce.

The water is boiled, and a portion then poured upon the isinglass, which, when dissolved, is poured into the remaining water, and all is boiled together.\* To this solution, filtered, is added—

12 grains of bromide of potassium, and  
8 grains of iodide of potassium.

\* The correction for temperature has hitherto, at nearly every place, except at Greenwich, been applied to magnetical observations, on the supposition that the decrease of magnetical force was proportional to the increase of heat; but this is found to be very far from being the case. The correction for temperature of the horizontal force magnet at Greenwich is represented by  $0.00009050 (t - 32) + 0.00000626 (t - 32)^2$ ; the second term here becomes very large, when the temperature departs much from  $32^\circ$ , and in Mr. Brooke's arrangement is not taken into account.

One side of the paper is then washed with this solution, and dried quickly before a fire. The paper thus prepared will keep in a dry place for two months.

When the paper is required for use, it must be washed with the following solution, in a darkened room with a yellow light:—

Crystalline nitrate of silver 50 grains  
Distilled water 1 fluid ounce.

To bring out the impression, the paper is washed with the following solution:—

Saturated solution of gallic acid 1 ounce.  
Acetic acid a few drops.

To fix the impression, first wash the paper well with water, then with the following solution:—

• Hyposulphate of soda 1 drachm.  
• Distilled water 5 ounces.

And, lastly, wash carefully with water, and leave the paper to soak for a short time. The impression is then fixed, and light may be admitted.

A Council Medal was awarded to Mr. Brooke for this beautiful application of photography to the registration of natural phenomena.

WILSON (No. 402, pp. 452, 453) has exhibited three Fox's dipping-needles, furnished with needles of 6½ inches, 4 inches, and 2 inches in length respectively. Those with the longer needles are identical in all particulars with those which have been used successfully on board of ships, both for the observation of dip and relative magnetic intensity.\*

PARKES and SON (No. 671, p. 467) exhibit a number of pocket-compasses.

GREEN (No. 446, p. 462) has exhibited several magnetic sun-dials, with metal and agate caps, adapted to every degree of latitude. They are mounted in boxes made of various materials. Mr. Green has also exhibited various other sun-dials, some of which are fixed in round mahogany boxes with levels and adjusting screws, and others fitted up for north and south latitudes; also several horizontal sun-dials, and ivory circular thermometers, with compass or magnetic sun-dials attached to them. Mr. Green also exhibits pocket-compasses with metal and agate caps, and others also with floating cards, &c., variously mounted in round boxes with improved hinges. Several compasses are fitted up in variously constructed boxes of ivory, brass, German silver, &c., together with others in the form of a watch, of various materials, some being made of leather, others in gilt and silver cases.

Mr. Green also has exhibited cone-compasses and brass gimbal-compasses, intended for use in small boats.

YEATES (No. 332, p. 446) exhibits a prismatic compass adapted to measure both horizontal and vertical angles, with spiral level attached in such a way as to be applicable in both cases.

#### Electrical Instruments.

The electric instruments are few in number, and there is not one adapted for the purpose of determining the quantity of atmospheric electricity for meteorological purposes. This is a matter to be regretted, as the present state of meteorology greatly needs a simple, inexpensive instrument, adapted for the observation of atmospheric electricity, and one which would be uniform in its action under uniform circumstances.

One exhibitor, WESTMORELAND, (No. 444, p. 462) has, however, the merit of exhibiting a gutta-percha electrical machine, which holds out the hope of obtaining electricity of tension on a large scale by the application of steam-power, and thus a motive force, which may serve for the movement of machines, or enable us to accomplish objects at present quite unforeseen, but which the habitual use of an electric power commensurate with that of lightning may bring into view.

WESTMORELAND (No. 444, p. 462) exhibits a gutta-percha electric machine. It consists of two rollers of equal diameters, placed one above the other, over which a band of gutta-percha, 4 inches in width, is stretched;

\* For description, see Illustrated Catalogue.

opposite to the axis of each roller, and on either side, are placed two brushes of bristles. There is a double conductor connected by a curved brass rod hanging over the top of the machine, similar in form to the conductor of plate-glass machines, and also a simple means of tightening or loosening the band, to correct the expansion and contraction of the gutta-percha.

It is stated that the electricity given off appears to be of high intensity, and, under favourable states of the weather, nearly as much in quantity as that from an ordinary plate-glass machine. The machine exhibited, when in good order, gave off sparks from about three-quarters of an inch to an inch in length.

This application of gutta-percha is quite new in practice,\* and indicates the discovery of a new motive power, which promises to be a means of obtaining a supply of electricity of almost unlimited extension: this application of gutta-percha opens a new field in electrical research well worth exploring. A Prize Medal was voted to Mr. Westmoreland.

WATKINS and ILL (No. 659, p. 466\*) exhibit an electrical machine with a glass plate of 3 feet in diameter, furnished with both positive and negative conductors; they also exhibit a dry pile apparatus, furnished with a pair of Zamboni's dry electric piles, with a tangent screw, for the purpose of regulating the distance between the piles, and their position with respect to the suspended gold leaf. This is a beautiful instrument.

They also exhibit a delicate astatic galvanometer, for estimating minute currents of voltaic electricity; the lower needle is surrounded by a coil of wire 230 yards in length and  $\frac{1}{16}$ th of an inch in thickness. It is furnished with a rack-work motion, and a microscope for reading. And they also exhibit Harris's thermo-electrometer, for estimating small currents either of atmospheric or voltaic electricity, by the heating of a fine metallic wire.

DELETTI (France, No. 160, pp. 1178--80) exhibits an electrical machine for medical purposes, furnished with an arrangement to vary the strength of shocks. It is simple and effective in its operation.

MEINIG (No. 437, p. 460) has exhibited hydro-electric chain batteries, consisting of the metallic combination of various galvanic elements; so arranged as to be very portable.

They are designed to be worn on the body for the purpose of effecting the cure of various chronic diseases by means of the electric current, which in its passage from one pole to the other passes through that part of the body encircled by the chain.

#### *Thermo-Electricity.*

In 1821, LUNCK, of Berlin, found that, if two metals of different kinds be in any way brought into close contact, and heated at the points, a current of electricity flowed through the metals, which continued passing in the same direction whilst the heat increased, ceased to flow when the temperature was constant, and flowed in the opposite direction on the cooling of the metals; whence heat was found to be connected with electricity, and like other natural forces, capable of mutual reaction.

SESS (Prussia, No. 482, p. 1078) exhibits a very large thermo-electric battery, with electro-magnet heating apparatus and apparatus for exhibiting chemical reactions.

A central ball of heated iron,  $2\frac{1}{2}$  inches in diameter, supported on a brass stand, radiates on five thermo-electric combinations, each composed of many elements united by soldering, and are enclosed in brass cylinders about 4 inches in diameter, and connected by copper rods with each other, either directly or indirectly, or through a coil passing round a core of soft iron. The circuit thus completed, the magnetic power is developed. Each cylinder has also a chamber for the reception of hot water or hot oil, whose radiation on a similar compound thermo-combination, placed as a diaphragm within the cylinder, develops the thermo-electric current. Honourable Mention was awarded by the Jury.

\* The electric power of vulcanized caoutchouc is even more powerful than that of gutta-percha, and is excited with singular facility.

HOFFMANN and EBERHARDT (Prussia, No. 88, p. 1053) exhibit an apparatus for showing the action of the earth's magnetism on electric currents, in illustration of the well-known experiments of Ampere, in which helices and frames of copper wire, delicately suspended, when in the act of transmitting the electric current, place themselves in the magnetic meridian.

#### *Application of Electro-Magnetism to the movement of Machines.*

The great discovery of Professor Oersted in 1819, to which we have before referred, opened a new field for philosophic inquiry, and, especially for the application of an active force, produced, without external influence, to the movement of machines. This application, which has since engaged the attention of scientific men, is pretty well represented in the Exhibition: although no great power has as yet been obtained, many important difficulties in its practical application seem to have been overcome, particularly by Mr. HJORTH (Denmark, No. 47, pp. 1359, 1360), and we cannot help flattering ourselves that the attainment of this mysterious motive force will soon be followed by the making it available for practical purposes.

JOYLE (No. 440, pp. 461, 462) exhibits an electro-magnet, constructed of a plate of well-annealed wrought-iron, 1 inch in thickness, 1 foot in breadth at the centre, and 3 feet at the poles, which are 3 inches in breadth. The iron is rendered magnetic by transmitting the voltaic electricity through a bundle of copper wire (50 yards in length and 1 cwt. in weight) with which it is enveloped; an armature, and a pair of tapered armatures, are also exhibited for the purpose of concentrating the magnetic force when the electro-magnet is excited by a feeble voltaic current, and of directing the magnetic action to any required object. The superiority of this over other electro-magnets consists in the attainment of much greater magnetic force from a given voltaic battery than has hitherto been procured. Its use is to magnetise bars of steel and compass-needles, to which it instantaneously imparts a larger and more regular dose of magnetism than can be obtained by the usual means. It may also be employed to exhibit the phenomena of magnetism and diamagnetism.

Mr. Joule also exhibits a surface electro-magnet, consisting of a thick piece of wrought iron enveloped by a bundle of copper wire. The exhibitor observes, that a battery of moderate power produces such a powerful attraction between the above electro-magnet and its armature, that a weight of more than one ton is necessary to be applied in order to draw them asunder. This illustrates the extraordinary attractive power of iron when fully magnetized.

HARRISON (No. 420, p. 455) exhibits an electro-magnetic engine which acts on the principle of the induced magnetic power of a compound coil of insulated wire conveying the current to a series of plates of soft iron, and attracting them within a suitable aperture.

As there is only one body of wire in connection with each coil, the retarding influence of the electro-magnets acting upon each other, after the current from the battery is cut off, is avoided, and by this arrangement the effects of the secondary currents are much reduced. The coils are made of short lengths of wire, and the whole are enclosed in metallic cylinders: it is presumed that a considerable saving in the consumption of the battery materials is effected. The advantages, Mr. Harrison says, are:—

1st. An almost unlimited power and length of stroke.

2nd. The greatest possible amount of power from the battery, by reducing the influence of the secondary current to a minimum.

3rd. Avoiding the retarding influence caused by the retention of magnetism in the ordinary method of application by magnets; and from the body of iron acted upon by the coils exposing a large surface, an instantaneous and powerful induction of magnetism ensues, and thus the highest speed is obtained.

4th. By the employment of a compound conducting material, a strong current of electricity is transmitted, and a much greater magnetic effect within the same space is obtained.

5th. The larger the iron plates, and the greater the power of the battery, the greater is the economy of this engine.

Knight and Sons (No. 453, pp. 462, 463) exhibit an electro-magnetic engine. This is probably the simplest form by which an electric current can be made to work by its action on permanent magnets, though not the most effective. Four coil-magnets are fixed rectangularly on an axis, and revolve within a circle formed of four fixed magnetized quadrants. The contacts are made and broken by rubbing springs on an axis (so it appeared on examination); the nicety of construction consisting in the adjustment of the moments of union and disruption, so as to obtain an effective difference of action always in the direction between the two opposite poles of the permanent magnet.

Knight also exhibits another electrical machine, in which a bar is alternately pushed and pulled, and so working on a crank and turning a fly-wheel. In all these machines the mechanism itself provides for the necessary alternate making and breaking of the circuits. It is probable that little power is obtained, for the greatest care appears to have been taken to destroy friction, by making the fly-axis revolve on friction-rollers.

Watkins and Hill (No. 659, p. 466\*) have exhibited an electro-magnetic engine. Two horse-shoe electro-magnets are alternately excited by two electric currents, and each as it becomes a magnet attracts one of the arms of a rectangularly bent iron bar, which is thus kept in a state of oscillation round a pivot from one magnet to the other. The ends of the bar carry rods working on joints which are connected with cranks rectangularly placed on an axis. Thus the dead point of one crank coincides with the quiescent state of its own magnet and with the active state of the other, and the axis is maintained in rotation with its fly-wheel. The magnet, bars, and crank are so arranged along the axis as to give room for the cranks, of which there are two, though, in fact, there might be any number of magnets and cranks working simultaneously.

The alternation of the circuit is kept up by a mechanism worked by the machine itself.

Allen (No. 413, p. 454) exhibits an electro-magnetic railway-train alarm; it consists of a copper chain, intended to be placed over every carriage, the connection between each being established by the guard-chains; on the circuit being completed, the ordinary steam-whistle discharges the steam. The arrangements are as simple as well can be.

Cresswell (No. 417, p. 454) exhibits an electro-magnetic engine for the production of motion; it consists of two pair of electro-magnets, between which a keeper vibrates and communicates motion to a wheel and crank.

Froment (France, No. 1609, p. 1254) exhibits an electro-magnet acting alternately, by elevating a lever, which communicates motion to a crank. He also exhibits a circular arrangement of coils, two of which are in action successively.

Breton (France, No. 1113, p. 1231) exhibits an electro-medical apparatus with a double current; but as this instrument is intended for medical purposes, and not as a motive power, it scarcely falls within the province of this Jury.

Hjorth (Denmark, No. 47, pp. 1359, 1360) has exhibited an electro-magnetic engine. It consists of two sets of hollow horse-shoe electro-magnets, conical inside, with a corresponding number of solid electro-magnets, which, by mutually attracting each other, make a double stroke of 4 inches in length. The power has been found, by means of a spring-balance, to be about 30 lbs. at the commencement of the stroke, when the distance of the respective poles is about half an inch, decreasing slightly by degrees as the piston enters the hollow electro-magnet. The current is broken by the end of each stroke, and the destroying effect of the spark prevented by moistening the surface of communication with diluted sulphuric acid; no repelling power is applied.

Mr. Hjorth also exhibits a diagram and plan for an improved arrangement, consisting of only one hollow electro-magnet, the respective poles of which are divided into three or more square rings, which are somewhat

conical inside, and are connected outside with the armatures (?) of the magnet, which form the connection between the respective poles. From the upper and lower part of the arrangement extend within four iron plates with ribs, which in the centre are connected with corresponding diamagnetic plates and ribs. These plates are applied for guiding the motion of the piston, and serve at the same time as a means by which metallic contact may during each stroke be established and broken between the piston and any one of the respective plates. For this purpose, four pairs of rollers are placed within the piston or hollow shafts, which are arranged on the four-way-cock principle, with a ring inlaid with a diamagnetic metal between the rings and shafts, that the magnetic bearings may be brought into contact either with the similar or diamagnetic parts of the same rings.

The required motion of these rings is produced by small cranks inside the piston, joined to the connecting-rod in such manner that each pair of cranks moves in opposite directions.

Whilst the engine makes a down stroke, magnetic contact is established between the north pole and piston; the polarity thus acquired causes it to attract the south pole. When the down stroke is performed, the magnetic contact between the north pole and the piston is broken by turning the upper pair of cranks in one direction, whilst similar contact is established between the south pole and piston by moving the lower pair of cranks in the opposite direction. A reciprocal motion being obtained in the above manner, the electric current passes continuously in one direction round the piston and each of the poles, the motion of the piston being reversed by simply breaking and establishing magnetic contact. On the piston passing out of the one pole it enters the other, and induces thereby, according to the law of the secondary currents, two currents in opposite directions, and thus both are neutralized. The advantages assumed are:—

1st. The obtaining a stroke of any length with one hollow electro-magnet, the piston being a moveable extension of either of the poles, attracted by a succession of polarities, the acting surfaces of which extend to the whole circumference.

2nd. The arranging the piston in such manner that it may be extended to any size, without its being heavier than a piston in a low-power steam-engine of the same size, the power being expressed in pounds per square inch.

3rd. A prevention of the destroying effect of the electric spark.

4th. A neutralization of the secondary currents and a prevention of their reaction.

The following table, as obtained by Mr. Hjorth, shows the attractive power obtained with a horizontal electro-magnetic engine of 16 inches stroke, the poles of the moveable magnet being separated 6 inches, or, in other words, the piston being 6 inches square:—

| Distance of the respective poles. | Inches. | The attractive force was | And the angle of magnetic force was | °     |
|-----------------------------------|---------|--------------------------|-------------------------------------|-------|
|                                   |         |                          |                                     |       |
|                                   |         |                          |                                     |       |
|                                   |         |                          |                                     |       |
|                                   |         |                          |                                     |       |
|                                   | 5       | 72                       |                                     | 75.58 |
|                                   | 4       | 80                       |                                     | 72.31 |
|                                   | 3       | 98                       |                                     | 67.22 |
|                                   | 1½      | 140                      |                                     | 50.12 |
|                                   | 1       | 160                      |                                     | 42.34 |

A Prize Medal was awarded to Mr. Hjorth.

### *Electric Telegraphs.*

As might have been expected, there are exhibited voltaic batteries; galvanometers; electro-magnets; telegraph wires; wires for submarine purposes; printing telegraphs; in fact, the Exhibition is rich with a large number of very ingenious contrivances, applicable to every stage of electric telegraphic communication.

The Electric Telegraph Company, which was established in the year 1846, have evidently used much diligence in possessing themselves of numerous patents, commencing with Cooke and Wheatstone's five-needle telegraph, patented in 1837, up to the present time. In the fine collection they exhibit are some of the most valuable inventions, in point of real practical utility, that have yet occurred; but they include also many forms of telegraph which, judging from their not being made use

of, have been, it is presumed, found to be of little practical value.

It would seem that the needle telegraph, giving conventional signals, has obtained a firm standing in this country; and with the recent improvements in the galvanometer, it has certainly attained a high degree of perfection.

The form of the needle in most general use is that of a small rhomboid, into which much magnetism can be imparted, and which vibrates with great steadiness and rapidity. It, however, has the disadvantage of parting with its magnetism much more readily than longer needles, and requires to be re-magnetised more frequently.

When we reflect how very few years have elapsed since all that was known upon this subject (now the science of the age) was confined to a few scientific men, and regard its subsequent rapid progress, and probable great extension,\* it cannot fail to be both interesting and instructive to trace briefly its progress, and to examine somewhat in detail the essentials of electric telegraphs, with the view of seeing how far such are attained in those exhibited. It is not the purpose of this report to trace the history of inventions, but one of its principal objects is to give merit wherever it is due, and it is hoped that the following attempt to classify telegraphs, being the first which has been made, is well within its province. In drawing it up we have to acknowledge our very great obligations to Charles V. Walker, Esq., the Telegraph Engineer to the South-Eastern Railway Company, for the kind assistance which he has freely given.

The idea of utilising the electric form of force, so as to have the means of rapid intercommunication between places far apart, is coeval with the discovery of the exceeding velocity with which this force travels through good conductors; and hence, as far back as 1782, we have a M. Lesage proposing to deflect twenty-four different leaves of gold, at the end of twenty-four distinct wires; and in 1787 we have a Mr. Lomond passing signals from room to room, by means of a Leyden jar and an electroscope, experiments useful enough as scientific illustrations, or as philosophical toys, but of no practical value. Indeed, so long as we were in possession of no other form of electric force than that which is obtained in a state of high tension from the joint friction of suitable bodies, there were no hopes, even had man been ready to take up such an invention, of an electric telegraph, properly so called. We find Reizen and Salva at the close of the last century, and Ronalds at the commencement of the present, doing their best to render this wild and wayward form of electric force subservient to their purposes; and the latter effectually controlling it within certain limits, and making a telegraph that did some actual work. It was not, however, until Galvani's discoveries had opened out a new field of electric research, which was so successfully trodden by Volta, when it was found that certain relations existed between heterogeneous bodies, attended always by the production of electric force in a new and much more manageable form;—it was not until this discovery of voltaic electricity that the idea of an electric telegraph became developed with any distinctness. We then perceive an advance; and although the applications that first occurred were sufficiently clumsy and impracticable, as compared with the knowledge we now possess, there was enough in Soemmering's decomposing points, in Coxe's decompositions, in Vorseelman de Heer's electric shocks, and in other original ideas, to prove that the prospect of ultimate success was still entertained.

But when Oersted had discovered that this new form of force, voltaic electricity, had a constant relation to magnetism, and that its presence caused the compass-needle to deflect according to unvaried laws; and when M. Arago had discovered that the same force would endow an inert mass of iron with all the wonderful prop-

erties of a magnet, we became possessed of powers, which only required rightly to be handled and controlled, for the solution of the problem; and when, further, Faraday had discovered, that the mere motion of conducting bodies in the neighbourhood, or within the sphere of magnetic influence, gave rise to electric force; and Pixii first, and Saxton ultimately and effectively had worked out this discovery, and had produced the magneto-electric machine, there was a choice of means for producing the actuating force, and we could use at our pleasure this or that means of generating, what is popularly termed the electric current. A third source from whence might be obtained the means of actuating the signalling apparatus, was found in Faraday's further discoveries of the induction of currents in one set of conductors, by original currents passing near them in other sets of conductors. It may be supposed that during this last stage in the history of electric telegraphs, extending as it does to this very hour, many unsuccessful attempts were made, and many discoveries were introduced to the public eye, only to be abandoned as futile, and as wanting many of the essentials to real success;—the name of these is almost legion.

The Exhibition contains many inventions which are most valuable. Perhaps it would be well to consider here the essential or fundamental points of an electric telegraph; they are three in number and are as follows:—

- I. The generation of the force.
- II. The insulation of the force.
- III. The utilization of the force.

We will proceed to speak of them separately.

I. *The generation of the force.*—In the majority of electric telegraphs in actual use, batteries composed of heterogeneous metals, moistened by a liquid or liquids, are employed for the generation of force. We find that Grove's combination of zinc and platinum, excited respectively with dilute sulphuric acid and nitric acid; Daniell's of zinc and copper with dilute sulphuric acid, and sulphate of copper; Smee's of zinc and platinized silver, with dilute sulphuric acid only; Cooke's original telegraph battery of zinc and copper with sand, and dilute sulphuric acid; Walker's graphite battery, in which the corrosion from gas retorts is substituted for the copper of Cooke's; and other forms, have been used by different inventors. But where a telegraph really requires the more expensive and complex form of battery first described, there is a *prima facie* case against it; for in the maintenance of a large establishment, the cost of such battery power would be proportionably great, and unless compensated by some very great advantages on the part of the telegraph would be regarded in no very favourable light. Siemens's telegraph (Zollverein 310A), for instance, is most ingenious and is well constructed; but whether it possesses advantages over other known plans, that will compensate for its requiring to be worked with Daniell's battery, remains to be proved. Again, though as a reading telegraph it should not hold this rank, its printing powers, as compared with other printing telegraphs, might be greatly in its favour.

The ordinary acid battery has been almost invariably used in England. It is the least costly in construction, and is maintained at the least expense: it remains active for a considerable time, but suffers ultimately more during its resting than during its working periods, on account of the combinations that occur between the sulphuric acid and the copper, with the subsequent decompositions. With graphite plates this defect is remedied. The Prussian telegraph has the peculiar advantage that the batteries, both at the sending and receiving stations, are simultaneously in the circuit; and for long distances it avails itself of battery power at intermediate stations. The American telegraphs, in like manner, throw local batteries into circuit to do the actual work. This peculiarity occurs in some of the English patents, but does not seem to have been introduced into actual practice.

Perhaps the most curious proposition for the conversion of battery power into language is that of M. Botto, whose signals depend on the number of pairs of battery plates employed to deflect the distant needle, and are interpreted

\* At the time of our writing, the wires are being laid from Dover to Calais, thus connecting the Continent with our system of telegraphic communication; and arrangements are being made to connect the observatories of Greenwich and Paris.

at the receiving station by turning on pair after pair of plates in the reverse direction until the needle comes back to zero, when the number of cells required to do this gives the letter or signal. The idea is original; but in order to carry it out the batteries must be precisely of equal power, and no portion of the force must be lost in transit.

The earth itself has been made to furnish a supply of electric force; in other words, a single pair of zinc and copper plates have been buried sufficiently below the surface to be in the wet subsoil, when the earth, saturated with water, represents the sand saturated with acid water, of an ordinary battery cell; by this means a current of low intensity is obtained, even when the plates are some miles apart. It was thought by some that this feeble current might be made available for telegraphic purposes, by laying one metal at one station and the other metal at another, and very exaggerated propositions were put forth. Steinheil rejected this mode of obtaining the current, which is only available, and that very indifferently, at the place where both plates are buried.

The means of turning on the electric force, or setting the current in motion, are as various as are the different inventions: in one case, consecutive depressions of a single stud are made, and a current is sent in one direction only; in another, handles or levers are moved in either direction, and two directions of current ensue; in another, the current is turned on in a constant direction, and the action of the instrument breaks and renews the circuit; in another, the whole force is sent along one wire, or is divided between two, and is directed this way and that as the case may be.

The magneto-electric machine is a constant fountain of force; it does not vary in power, as do batteries, nor ultimately become exhausted, but remains for an unlimited time capable of generating the induced electric current. It consists essentially of a set of powerful permanent magnets, and a coil or coils of copper wire wound upon iron cores; the ends of the copper wire being led off to adjustments proper for distributing the force in the right direction. The current is obtained by briskly moving the coils in presence of the magnet, making, in fact, the conducting wires to move among the lines of magnetic force. Where single currents are required, one motion of a lever on the other arm of which the coils are fixed, gives an instantaneous current. Where, as in Wheatstone's instrument, a number of consecutive currents are required in rapid succession, the coils are mounted on an axis which can be made readily to rotate, and to rest at any required point. Where, as in Henley's instrument, the force is required along one or other, or both of two wires, coils are mounted on levers near each end of bar magnets. Steinheil, Dujardin, and Hatcher are among those who have employed the currents from this source. When the current of high tension, induced from an ordinary current of low tension, is wanted, a cell or two of the more constant form of battery is employed to pass a current along a coil of stout wire surrounded by a long coil of thin wire, which latter is permanently in the telegraph circuit, and out of which is generated the active force.

II. *The Insulation of the Force.*—This is unquestionably the most difficult part of electro-telegraphy. It has engaged the attention of practical men from the onset. It is in vain that an abundant supply of electricity is obtained; it is in vain that the best measures are contrived for turning on this supply, and vain is the expenditure of thought, and contrivances for converting this electricity into a representation of our ideas, if the means are defective for conveying it in its integrity to its destination. Electricity of high tension, such as was employed for the early illustrations of signalling, might have been sufficiently well passed by Lomond from room to room, if his wires were carefully suspended, and the atmosphere tolerably dry; but when Ronalds proposed to pass the same agent along a distance of only 175 yards, he was compelled to surround his wires by thick glass tubes, well coated with wax at the joints, and placed underground in wooden troughs lined within and without with pitch. Frictional electricity, as is well known, requires

perfect insulation to prevent it passing off in the form of the electric spark. Weber, in 1833, had found the voltaic current to be retained in wire of about a mile and a half in length, which was merely suspended from the steeples and house-tops of Göttingen. Steinheil, in 1837, erected and worked his telegraph at Munich, through a distance of about six miles, with no other insulation than a piece of felt placed between the wire and the support; but he found the insulation imperfect, and the more so in wet weather; and saw clearly that the force would have been altogether dissipated, had the circuit been longer.

The suspended wires are, at the present time, occasionally insulated from their supports by glass, but more commonly, as in England, by hard, well-glazed stoneware. Much ingenuity has been exercised in the form to be given to the insulators, of which there are many in the Exhibition. The barrel-shape, pierced longitudinally, universally prevailed here until long circuits called for some more perfect form; and now in the bell or mushroom, the bold, open-mouthed cone, or other analogous forms, we can discover that the actuating idea has been to keep the points of contact dry, and to let the interval between the wire and the pole be a maximum. WALKER (No. 430) has gone a step further, and has placed a closed roof over his insulators. Cases occurred in which it was found convenient, even in the early days of telegraph, to lay the wire on or near the ground, and eventually under the public streets, when it was covered with cotton saturated with tar and pitch, and protected by leaden pipes. This was found to be very inefficient, nor did much better success attend the use of caoutchouc, which was not only expensive, but neither manageable nor durable under the conditions to which it was subjected. By a most happy coincidence, gutta-percha appeared in the market at the time, when resins and varnishes, and the known gums had been tried and found wanting. It was appropriated by Siemens in Prussia, who employs buried wire very largely, and by Walker in England, who used it at first between Dover and Folkestone, and now extensively in tunnels and under water, and who demonstrated its value for submarine purposes, by sending signals to London with two miles of gutta-percha wire (a piece of which wire is exhibited) in circuit, in the sea at Folkestone, in January, 1849. The street wires and tunnel wires, as well as those submerged in England, Belgium, America, and elsewhere, are now perfectly insulated by a coating of this valuable material. It is applied warm, either by powerfully pressing it upon the wire, or by causing it to follow the wire through a hole of the given size. In the streets the wires are sunken, and protected by being enclosed in iron-pipes, which proves to be very necessary, for in Prussia, where they are buried without protection, they suffer so frequently from the attacks of vermin, that it is in contemplation to suspend them as we do.

Under rivers or harbours they are protected by pipes, or are secured in a mass of timber, or otherwise. In all the tunnels on the South-Eastern line, Mr. Walker has laid them in grooved boards, which method has been since followed by the Telegraph Company, and is also adopted by the Belgian Government on their lines. It is unquestionably the simplest and safest of all methods.

The protection required for submarine wires is very great. The wire, by means of which a telegraph communication was obtained for a few hours between the coasts of England and France, was not calculated, neither was it expected to remain perfect for many days. It was clearly not laid down with the intention of remaining permanently, but for some special object. It was a copper wire, coated in the ordinary way, but thickly, with gutta-percha, and where it reached the shore, protected by a leaden pipe.

MCMAN (No. 421, p. 455) has exhibited some excellent specimens of his process of covering gutta-percha wire, first with cotton and then with an outer coat of gutta-percha, and finally with lead, in the application of which latter the cotton becomes impregnated with gutta-percha from the outer coating.

Wrought iron chain-pipes, with swivel joints, have been constructed by WASHAW (No. 419), and are exhi-

bited as means of protecting submarine wires. Brett shows a sort of vertebrated hollow iron chain of considerable strength, which is proposed to be built about the wire. But there appear practical difficulties in the application of these plans. We see some insulated wire, protected by a strong net-work of wire woven over it, which imparts great strength and elasticity, and will often be found useful. The wires prepared for establishing communication between England and France, are coated first with gutta-percha, and then twisted together, being four in number, thickly covered with rope-yarn saturated with tallow and pitch, and finally protected with galvanized iron-wire of the thickness of a quarter of an inch.

A plan worthy of commendation for its simplicity, and for combining the leading essentials of a submarine wire, has recently appeared. A chain cable of sufficient strength to resist any strain to which it might be exposed, is galvanized; gutta-percha wire is covered with tape, or a similar material, saturated with creosote and other matters offensive to animalculæ; outside this is another coating of gutta-percha, and around the whole galvanized iron wire is wound, like the wire of a harp-string. One or more wires are enclosed in the outer coating of gutta-percha, before applying the galvanized wire, as may be required. The chain is arranged regularly, that is, with the links alternately vertical and horizontal; and in the four corners or angles presented, is laid one of the wires prepared as above, which is retained *in situ* by simple slips of galvanized iron, from which it can be readily released. The full strength of the chain is thus increased by the addition of the wires, and the combination is very elastic and manageable.

Insulation is not a little dependent on the state of the circuit, that is to say, on the relative amount of resistance, opposed to the passage of the force. In short distances defective insulation is not much felt, for the resistance offered by a few miles of wire, which is a very good conductor, is far less than that presented by the films of water or other bad conducting material near the insulators; the relations of these resistances vary with the length of the wire, and also greatly vary if the resistance of the wire is increased by badly-made joints. In early days the lengths of wire were joined by mere contact, and the pressure of a nut or bolt; and the winders by which the wire was tightened formed part of the circuit. This plan was found by no means to satisfy the conditions essential to long circuits; and now the joints are made with scrupulous care, and the lengths of wire are soldered together from end to end, the winders not being allowed to enter the circuit.

Steinheil had discovered, in 1837, that it was not necessary to lead a wire from each pole of the battery, to the respective sides of the telegraph apparatus at the distant station, as would be done in all experiments on a small scale, but that the conducting powers of the earth could be advantageously substituted for one of the wires. The saving of one out of every two wires, important though it is, is not the only advantage derived from this discovery. The earth is found so far to surpass the wires themselves in conducting power, that it adds nothing to the resistance; so that equal effects may be produced at double the distance with the same initiative force. The resistance therefore for any given distance is one-half, and the tendency towards defective insulation is reduced. The earth acts as the return wire, to any given number of distinct wires, without in the least affecting the regularity of the action of any of them.

III. *The Utilization of the Electric Force.*—Almost every effect by which the presence of electric force is made manifest, has been in turn enlisted for the purpose of transmitting our ideas to a distance—not excepting even the heating effect of electricity, which have been employed by Horn to ignite wire and singe signals on paper.

1. The spark was employed by Reizen, who pasted strips of tin-foil on glass, and cut out the letters by dividing the strips, which intervals were illuminated by the spark. Salva used the spark, but how converted into language was not known.

2. Recession of similarly electrized bodies occurred to

Lesage, who proposed twenty-four wires, with a pair of gold leaves at the end of each; one or other of the pairs was to diverge by an electric charge. Tribouillet proposed something similar, with only one wire and conventional signals. Lomoid used a common electrical machine and a pair of pith balls and conventional signals. Ronalds employed pith balls, and two well-regulated time-pieces, which carried round similar discs of signals, each presenting the same signal at a fixed point at the same time. He deflected his pith balls, and discharged the electricity, allowing them to fall when the right signal arrived at the given point.

3. The *physiological effects* of electricity, in other words the electric shock, was proposed by Vorseelman de Heer, and actually tried in 1839. He had ten wires, and ten keys or studs, on which the fingers of the hands were to be placed; and the shocks felt in the various fingers constituted the signals. Instead of an alarm to call attention, the clerk had merely to connect himself up in the telegraph circuit, when he might safely rely on being feelingly reminded when his attention was required. O'Shaughnessy proposed giving shocks from the induced current, one shock and a group of shocks being the distinctive marks, and each station being provided with time-keepers, having a disc of signals, a shock to be given when the index pointed to the letter intended.

4. The *decomposing powers* of electricity suggested themselves to Soemmering. Some twenty or more wires terminated in gold points, within a vessel of acid water, and according as the circuit was made by one or other of the wires, a small stream of gas ascended from its terminating point, and hence the alphabet. He also contrived that an inverted cone should collect the gas, and would then float and cause a little ball to fall on a detent to liberate a clock mechanism and a bell. Coxe proposed the decomposition of water, but gave no plan. Davy impregnated cotton with hydriodate of potassa and chloride of calcium, and having marked it off in chequers, secured it on a cylinder that rotated by a clock movement. The current has to be directed through the cotton, and to produce a spot; the chequer on which this spot fell determined the signal. The clock-work was released by an electro-magnet, actuated by a current in other wires. Bain's printing telegraph depends on the same principle, applied, however, to the decomposition of more sensitive bodies, and reduced to actual practice. He acts upon a mixture of sulphuric acid and prussiate of potash, with which he moistens paper bands. The paper is interposed in the circuit, and receives a mark wherever the current passes and decomposes the solution. The alphabet consists of a combination of short and long marks, produced respectively by instantaneous currents, and by currents of short duration. These currents are sometimes sent by hand, by mere making contact; at other times short and long holes are punched in a dry paper band, and this is drawn by clock-work between the metal point and cylinder, which closes the circuit, and thus the current is cut off, when the sound part of the paper intervenes, and passes when the presence of a hole allows the point to touch the cylinder, and complete the circuit the moist paper receiving the spots is made to move on at a like rate. Bakewell places his solution in like manner in a paper band; but he writes his messages with varnish upon tin-foil, and places this between the point and cylinder, and causes the latter to revolve, and hence the current is intercepted wherever the varnish intervenes; the moistened paper revolves at a like rate, and both progress axially, so that a fac-simile occurs of what had been written.

5. The *galvanometer* has been most successfully pressed into telegraph service, and forms the essential part of the needle telegraphs which have obtained so marked a reputation in England.

Steinheil used one galvanometer coil containing two needles, which carried ink-cups, and made dots as they were deflected. Alexander had thirty wires and galvanometers, the needles of which carried screens and disclosed letters on their being deflected. Schilling, according to one account, used thirty-six wires, and galvanometers, and, according to another account, only one;

and he had a plan for checking the oscillations of the needle. Davy showed, in 1836, what was apparently a needle telegraph, somewhat similar to Alexander's. Gauss and Weber had a single needle telegraph, the deflections to be observed with a spy-glass. Fechner suggested twenty-four galvanometers and their respective wires. Botto's plan of one galvanometer, whose deflections were to be neutralized by an adverse current, has been already named. Mason suggested a single galvanometer. Galton has published a description of a very complex apparatus, the electric parts of which are three galvanometers, whose office is merely to present needles as mechanical obstacles in certain spots among a train of machinery. Cooke and Wheatstone at first used five needles on a lozenge-shaped dial, two of which were always used for a signal; and the letter was found where the points produced met. The needle instrument now in common use, and in which one or more deflections of either or both needles in one or other direction, gives all the combinations necessary for conducting rapid correspondence. The details of these instruments have been much improved, and there is little wanting to make them perfect. There is also a single needle instrument, which gives all necessary signals, but not so rapidly. The success of the needle telegraph has led to many modifications of the galvanometer. Brett and Little coil the wire on a circular bobbin, and make a crescent-shaped needle, the poles of which are properly presented to the coil; instead of reading from the prime motion of the needle itself they read from indices, which are moved by a tap from the needle. Highton's galvanometer needle is horse-shoe shaped, and the coil also circular and duly adjusted to the needle. He reads from an index carried on the same axis with the needle. He has also three needles, each carrying a screen, transpinned in such sort that by a combination of motions twenty-six different letters can be exhibited to the eye. Little has suspended an ordinary needle to the pole of the magnet, and within a tube of alcohol. The galvanometer coils are flat bobbins.

The *electro-magnet* has been used by Bain, Bakewell, Barlow, Breguet, Brett, Cooke, Davy, Dering, Dujardin, Garnier, Hatcher, Henley, Highton, House, Lodefink, Morse, Nott and Gamble, Palmieri, Siemens, Smith, Vail, Wheatstone, Wishaw, and others. In the hands of some of these inventors it has been made to give direct signals; for instance, in Henley's instrument the armature carries the index needle, and the combination of the deflections of two needles gives the alphabet. In Morse's the armature carries a point which impresses permanent marks on paper; it is also connected with wheel-work for moving the paper onward. In Dering's the magnetized armature carries the index needle. In Dujardin's the armature carries a point that dips in ink and makes dots. Siemens' print, by the direct blow of a hammer carried by the armature, although his type is brought in by a secondary action. In the hands of others it communicates motion to the index, as in Breguet's semaphore instrument, where the armature acts upon scapewheels, and gives to the indices the eight positions of the ordinary semaphore. In Nott and Gamble's the armatures carry claws that draw a wheel round, and with it the index, till it points to the given letter. In Siemens' the armature acts in a similar manner. We also find a third class of instruments in which the motion of the armature releases a detent, and liberates a clock-train, the motion of which produces the signals. Cooke and Wheatstone's alarm is sounded in this way, the hammer in some cases representing the pendulum bob, and in others, being carried on the produced radius of one of the wheels. Brett prints by the successive action of a detent liberating clock-work. It would be no easy task to follow the several inventors through the essential details of their apparatus; nor would it be very practicable to prepare a complete list of all that has been either conceived, contrived, or constructed, together with all that has been tried, and proved successful or otherwise in this wide field of research. It may well be supposed that many of the plans to which we have referred, have existed only in imagination—that many are

absolutely useless—that many others are too complex for actual service—that some perform badly and with uncertainty that which others accomplish rapidly and successfully.

The French Government required signals to resemble those of the old semaphores, and they have extensive codes. We have in England preferred conventional signals, thinking it better to train young men to read a new alphabet than to have an index going through the comparatively slow operation of pointing to every letter. In Prussia the latter plan is preferred. There has been also a choice between reading and printing instruments; in America the latter have prevailed; in England the former. But whatever be the actual sign by which we obtain possession of the ideas transmitted to us, it would seem that the instruments that have obtained a standing, are, almost without exception, those whose action is direct, and are not the result of any extraneous mechanism.

We will now proceed to a careful description of the several telegraphs.

THE ELECTRIC TELEGRAPH COMPANY (pp. 477\*, 478\*) exhibit many telegraphs.

I. Patent 1846, a rhomboidal needle. The galvanometer coil is in two halves, mounted on arms, which are made to open for the reception of the needle, and to close again. On the same axis is mounted the index-needle that is presented to the eye on the face of the telegraph, and which oscillates between ivory studs. The studs are now made moveable, as first proposed by Charles V. Walker, Esq., Telegraph Engineer to the South-Eastern Railway Company, for the needles to work between, so as to keep the neutral position, by adjustment, half way between them during periods of magnetic disturbance.

II. WHEATSTONE.—The instrument marked "Magnetic-electric Induction Machine," consists of a strong horse-shoe magnet, of eight plates, and 10 inches from either pole to the centre, fixed on a board; over it is placed a handle, which raises and depresses two coils of soft iron core and armature. On breaking contact, by depressing the handle a current of momentary duration passes out from one coil along the wire to the other in one direction. This gives a single impulse only, and always one way; and is used to excite an electro-magnet, and ring a bell.

III. HATCHER'S magneto-electric induction machine to send currents *ad libitum*, in either direction. This is effected by the same application of coils to a horse-shoe magnet and breaking contact; but there are two handles, and according as one or other is used to break the contact, cross communication takes place. "Hatcher's Current Director" affords a mode of making and breaking contact by cross communication, as an appendix to any telegraph. In this machine the horse-shoe is 12 inches in length, and consists of eight plates.

IV. WHEATSTONE'S patent rotating induction machine, for working the disc telegraph (1841). A dial wheel with spokes and letters. Each letter as it is wanted is brought to a given point. The wheels work a pinion, which causes a pair of coils and armatures only the poles of a great horse-shoe magnet. Every letter brought past the given point makes half a revolution of the coils and breaks, and renews the circuit opposite ways. The currents thus established and sent off to a distance, pass through coils and actuate local electro-magnets, which alternately attract to and from an iron plate, and thus alternately release and lock a detent. A clock, driven by a spring or weight, being thus allowed to act at intervals, drives round a dial-hand, click by click, at the other station, and thus imitates the motion of the original dial-wheels. This clock, however, requires to be wound up, and it does not seem to provide for any notice being given when it is down.

V. BARLOW'S patent, 1848. A printing telegraph, consisting of a circle of letters brought round in succession till the letter wanted comes to a given place; contact is broken as each letter passes, and the current is reversed; the current so established act (at the other station) as four coil magnets, &c., between which a soft iron bar is thereby caused to oscillate, and to lock and

unlock an escapement, and cause a wheel to imitate the motion of the letter circle. This wheel brings round type punches, and on coming to rest, a hammer strikes the punch (worked by a coil-magnet), and impresses a paper ribbon, which is drawn uniformly along by clock-work.

VI. **NORT and GAMBLE's** telegraph presents two double alphabets; the one direct, the other inverse, and the digits are many times repeated on a circular dial, having an index, which moves with a step-by-step motion, and is brought to rest at the letter required. The force is derived from the voltaic battery; and current after current is set in action by the successive depression of an ivory key by the finger; it is made available by means of two U-shaped electro-magnets, acting simultaneously and in the right direction upon two levers, furnished with clicks, which work in a scape-wheel that carries the index, and propel it, notch by notch, as each contact is made.

VII. **HATCHER's** induced current machine, patent 1847; to produce currents in either direction by one motion of a handle.

Two make and break circuit arcs of brass and ivory-pieces, alternating with rubbing-springs, so arranged that when the springs on the right arc connect brass and brass, that on the left shall connect ivory and ivory, and *vice versa*. In either state, a depression of the handle breaks contact of coils of magnets, and throws a shock along the wires.

VIII. **COOKE's** patent, 1847. A portable telegraph, for the guard on a railway to receive messages in case of an accident, by making a contact with the regular wires along the line.

IX. **BÄTT and LITTLE's** patent. A conventional alphabet by needle oscillations, in which the handle at the first station, by working to and fro, establishes alternate cross communications, and thus directs the current alternately one way or other. There are two needles, but each needle oscillates in only one direction.

X. **WILKATSTONE and COOKE's** patent, 1840. In this arrangement the rapid alternation of circuits is effected by the dial-wheel turning a pinion, half of ivory and half of brass. The motion of the dial-wheel is imitated at the second station by an escapement-wheel, driven by the oscillation of a pair of detents worked by a four-coil local magnet apparatus, alternately urging a piece of soft

of which  $b$ ,  $b^2$ ,  $b^3$  is an inactive combination arising from a quiescent position of all the needles; a conventional alphabet may be constructed by a simultaneous use of any three of the combinations, except  $b$ ,  $b^2$ ,  $b^3$ ; thus,

$|||$  may indicate A;  $\diagdown \diagup$  may indicate B; and so on.

This principle is worked out by a system of cross combinations of three batteries, acted on by keys, as in a piano. The key  $a$  being depressed brings simultaneously into circuit the three positive currents;  $b$  brings into action the positive current of battery 1 and 2, and throws battery 3 out of action.

Another application of this principle to a reading alphabet consists of three pendulums, each carrying screens, with orifices pierced so that by each combination (bringing the screens into twenty-seven different relative positions behind one another) only one orifice shall be exposed, showing the desired letter. This principle is also applied to printing telegraphs; thus, no type can be pressed till three conductors conspire, and these are directed and ensured by the three positions of the needles, and, which comes to the same thing, by the combinations of the three currents creating twenty-seven electro-magnets.

**HIGHTON's** patent of 1850. Use of a permanent magnet to keep up the magnetism of a soft-iron moveable magnetic needle (as a security against lightning destroying the magnetism of this needle), by continually re-magnetising it. A lightning strainer is also exhibited. The circuit-wire, covered only with bituminous paper, is made to pass through a box of iron filings. This is found

iron to and fro. It is an imitation telegraph, and reads the actual letters.

XI. **HATCHER, 1847; electro-magnet printing telegraph.** The usual reciprocating action between coil-magnets, instead of carrying round a wheel, makes a series of dots on paper constituting a conventional alphabet.

XII. **BAINS' patent, 1846; chemical printing telegraph.** Signals are given by marks arranged in one line of different lengths and intervals by the pressure (on prussio-muriated paper) of a link of iron wire, which deposits prussian-blue, the paper being adjusted by clock-work.

A Prize Medal was awarded to the Electric Telegraph Company for the exhibition of this fine series of telegraphs.

The **BRITISH ELECTRIC TELEGRAPH COMPANY** (No. 432, p. 459) exhibit **HIGHTON's** patent, dated 1848. The principle is economy of wire by encircling the poles of a horse-shoe rather than going round a straight magnet. The power gained is stated to be as 7 to 1. An improvement is also claimed in the mode of throwing two lines into connection by a single spring and cross bars, so as to halve the risk of a spring breaking. Thirdly, carrying a coil all round a horse-shoe, and thus causing each part of the magnet to act on each part of the coil; but this is in opposition to the first principle, so far as a saving of half the wire is concerned. Fourthly, application of the principle of the arrangement of the letters on the rim of a dial-plate, not according to alphabetical order, but according to frequency of occurrence in writing; but arrangements of this kind have been in use in printing-offices, on the principle of the more frequent letters being placed the most within reach. Fifthly, a ready mode of bringing the needle on the alphabetical-dial to zero, by touching a key. The step-by-step current which works the needle round is thus thrown out of gear, and its power thrown on another magnet, creating a force which lifts the detents of the escapement, and lets it pass round to the stop in the same direction. Sixthly, is exhibited a very ingenious piece of mechanism for locking the printing-wheel, so that it cannot by any possibility run on two letters for one motion of the alphabetical needle. Seventhly, since  $3^3 - 1 = 26$ , the number of letters in the alphabet, and since  $3^3 - 1$  is also the number of electric combinations of three oscillating needles; thus—

to be insulation enough for the galvanic current, but not for the tension electricity of lightning, which is therefore carried into the earth by the filings.

The use of the secondary battery, the  $3a - 1$  combination principle, is made applicable to printing, by touching keys carrying the letters to be printed; and a patented application of the chemical principle, that sulphate of alumina in solution may be advantageously used, instead of sulphuric acid, to keep the battery in action.

A Prize Medal was awarded to the **BRITISH ELECTRIC TELEGRAPH COMPANY** for the exhibition of their ingenious telegraphs.

**HENLEY** (No. 428, pp. 457, 458) exhibits two powerful compound linear bar magnets. The electric force is produced by a semi-rotation of a double electric coil and armature opposite either pole. The movement is extremely simple and neat, and the shock delivered very powerful. It has worked through 560 miles of wire, also through 60 feet of water. Experiments on the Serpentine were made, when several feet of the wire under the water were stripped of the gutta-percha coating without dissipating the current; and when (as the Jury were told afterwards), on further trial, the wire was divided under the water, yet the shock passed between the ends sufficiently to deflect the needle effectually.

The principle of using permanent magnets as a substitute for a battery is not new. At Göttingen, in 1839, Sir John Herschel was present when Gauss telegraphed from his house to his observatory by its means.

This is a double-needle telegraph, but the needles move

only in one direction. The magneto-current employed actuates electro-magnets, the armatures of which carry the index-needle, and move it as they move. These currents do not need so good insulation as do battery currents.

A Council Medal was awarded to Mr. HENLEY.

J. BRETT (No. 429, p. 458) exhibits an electric printing telegraph, which consists of two parts, called by Mr. Brett the communicator or key-board, and the printing machine; the former is supposed to be at the station from which intelligence is to be transmitted, and the latter, the place to which it is to be sent.

The machinery is propelled chiefly by the power of weights, or by ordinary clock-springs. The motion of the printing-machine is regulated by the galvanic current, by means of an escapement, and which requires much less power than is necessary to impel the machinery: thus both the advantage of the instantaneous action of the current, and the greater power of the weights, combine to accomplish the work for which this machine is designed.

The key-shaft is about five inches in length; the finger-keys act upon pins by means of rods and levers. The circuit-wheel is fixed to the axis of the key-shaft, which works upon a hollow axis with ratchet-wheels and clicks, so as to move forward in one direction with the circuit-wheel. Immediately after it has revolved the desired distance, a number of points, to correspond to the letter or character indicated by the finger-key, and required to be printed by the printing-machine, are released and return to zero, by means of a pulley and weights, independently of the circuit-wheel. The type-wheel is so attached to the key-shaft that a message may be printed in duplicate.

There is another arrangement by which the type-wheel or wheels is attached to a hollow axis, which carries the type-wheel backwards or forwards by a pinion acted upon by a train of wheels in connection with it: this train communicates motion to an arbor, to which a disc is fixed firmly: against the disc a ratchet-wheel is placed, mounted loosely on the arbor, between a fixed washer, and adjusted by a spring-catch, so that it can turn a short distance only on its axis. A slot is cut in the disc of this ratchet-wheel, and also through the adjoining disc, in which a pin works, connected with the tail of a click: this click is so adjusted as to catch into the teeth of the ratchet-wheel. Therefore, when the click is locked into one of the teeth, it causes the type-wheel to travel with the axle and pinion; but when the click is released, the type-wheel returns to zero, by the assistance of a pulley with cord and weight, or of a spring connected with the hollow axis. A lever is put into action by a pin attached to the common wheel of the printing train of wheels, and by its means the type-wheel is returned to its starting-place immediately after a letter or sign has been printed. Mr. Brett considers this arrangement very important, as it insures safety from the derangement to which the type-wheel, by a continuous step-by-step movement, is liable, on account of the accumulation of errors, arising either from atmospheric or other causes. From the momentary effects of lightning or atmospheric influence the machine immediately corrects itself, and the sense of the subsequent correspondence is not disturbed.

The train of wheels which give motion to the type-wheel is controlled by means of a secondary train of wheels, fixed to the back of the frame-plate, which controls and reduces the force of the escapement, and relieves the galvanic or magnetic power required for its regulation.

The type-wheel upon this arrangement may have any desired number of letters and characters without retarding the operation, as they would be so economically placed in the order fitted for their general application. Mr. BRETT has adopted an arrangement of letters on the type-wheel in the order of frequency of occurrence. The arrangement is as follows:—e, t, a, i, o, n, s, h, r, w, a, l, c, f, m, e, u, b, g, p, j, y, k, v, z, q, z.

In Mr. Brett's patent of 1845 the key-shaft was worked by means of a bevelled friction-wheel, set in motion by a train of wheels and a weight. The barrel was made the

length suited to the number of the finger-keys, and the pins were fixed in a uniform helical row, extending its entire length. In the arrangement exhibited, the circuit-wheel is fixed to the end of the key-shaft, as before stated. Connected with this wheel are two pieces of metal, which form the conductors of the current; one of these rests upon the periphery, and the other upon the collar of the circuit-wheel, being alternately upon one of the teeth and over one of the spaces. Whilst resting on the tooth it completes the circuit, and when over a space the circuit is broken, and so on alternately.

In connection with the printing train of wheels of the printing-machine, is an eccentric or cam-wheel, which revolves upon the shaft, and is connected with an hydraulic regulator; so that when a piston is raised by the revolution of the type-wheel, a partial vacuum is formed in the valve-chamber, and water passes through holes into the chamber, and momentarily takes off the dead weight of the piston, and some of the friction of the lever, from the escapement. On the type-wheel being arrested, a lever descends, releases the cam-wheel, and the paper is pressed against the letter upon the type-wheel.

Plumbago or vermilion is preferable in use to printing-ink, as it does not require replenishing for a considerable time.

Mr. Brett also exhibits a small instrument which he calls a pocket communicator, designed for the use of guards of railways, to communicate with the nearest station on the occurrence of accidents, or on assistance being required. In use it is placed in connection with the lines on the railway, and a galvanic battery on the tender, the wheels of the carriage completing the circuit.

It consists of an axle, to which is fastened a ratchet-wheel, over which is fixed a circuit-wheel, with teeth and spaces suited to the number of letters and characters required. On its face is placed another ratchet-wheel, which causes the circuit-wheel to rotate when the click is put into operation, by moving forward a handle, connected with which is a pointer, by which the letters or signs are pointed out.

The arrangement admits of a double circuit-wheel being employed, for the purpose of reversing the poles of the battery, and thus changing the direction of the current of electricity.

An electric circuit regulator is also exhibited by Mr. Brett. Its purpose is to give a controlling power over all the stations on any line of electric telegraph, so that any important telegraphic information could be transmitted to one or more distant or intermediate stations, without the knowledge of such communication transpiring to any other place than the one intended; the other stations on the line being put out of circuit for the time, by means of a separate wire in connection with a very small apparatus at the different stations. This apparatus it is necessary to construct with a full knowledge of the number and relative importance of the stations upon the line, for the purpose of making the calculations correctly: it will be necessary to exemplify this. Take, for example, five stations.—London, Dover, Calais, Amiens, and Paris; and suppose the remaining stations to indicate upon the dial a *universal* communication with all the five stations. Ten other divisions will give all the changes of one station to another, thus:—London to Paris, London to Dover, London to Calais, London to Amiens, Calais to Amiens, Calais to Dover, Amiens to Dover, Paris to Dover, Paris to Calais, Paris to Amiens and London, Calais and Paris; making in all twelve points or changes. At each of the stations should be a small apparatus having a dial, similar to a watch, having indicated upon it the number of points, or the names of the respective stations. At the number indicated a small hand or pointer would show that station which was engaged with another in the occupation of the line, as all these would be acted upon simultaneously; and thus any unnecessary interruption would be prevented.

By the use of Mr. Brett's telegraph, communications are made in any language, and printed upon paper with considerable rapidity and precision; the paper and ink are self-supplying, and sufficient may be placed in the apparatus of both to last for some time. Mr. Brett says, that

the letters may be printed at a greater speed than a well-practised person could write them, and that a clerk, after some experience, might manipulate upon the finger keyboard upwards of 150 letters per minute.

Mr. Brett has also exhibited a specimen of the line used in the first experiment, across the Dover Strait, after having been submerged in very deep water for more than six months, and is part of the same wire through which the first galvanic current was transmitted from the coast of England to that of France. The experimental line was formed of a single copper wire, insulated by a layer of gutta-percha about five-eighths of an inch in diameter.

Mr. Brett also exhibits a specimen of wire cable. This is a portion of a permanent line, now being laid down

from the South Foreland to Sangatte, near Calais; the core of the cable is formed of four copper wires (No. 16), each of which is insulated and covered with two separate layers of gutta-percha. As in the experimental wire, the tightening of the line elongated it to a considerable extent, and caused the gutta-percha to divide, so destroying the perfect insulation of the wire; it was therefore resolved to obviate this source of failure by twisting the four wires together spirally, before encasing them in the hempen yarn, well saturated with tar and bituminous compounds, with which they are completely enveloped. The core thus formed, is protected by ten galvanized iron wires (No. 10 gauge) twisted together, the whole composing a cable  $1\frac{1}{2}$  inches in diameter, as shown in the annexed cut.

Mr. Brett also exhibits a vertebrated iron tubular cable. This is designed to protect a cable of submarine telegraphic wires, when situated near the sea-coast, from sustaining damage by anchors, or by casualties likely to

occur when situated in the vicinity of shipping, and may be made of great strength, and of considerable curvature, without either damage or derangement, as in the following figure.

One of the iron cables exhibited, is constructed with the addition of a chain of links, for the purpose of giving

a greater degree of strength in dangerous situations, as shown in the annexed figure:—

A Council Medal was awarded to Mr. BRETTE.

BAIN (No. 434, p. 460) has exhibited an electro-chemical telegraph, depending, like that of Mr. Bakewell's, on the development at a distance of the chemical effects of electricity. The effect produced is the precipitation of Prussian blue on paper, duly prepared by impregnation with prussiate of potash and weak acid, on the contact of a steel pointer, at the signal station; this contact being determined by the attraction of an electro-magnet on the arm which carries it. The breaking and renewal of contact at the station of departure, is effected by the interposition of a band of paper, drawn uniformly along by clock-work, and punched out in holes and slits of different lengths, which allow of more or less prolonged contacts, in conformity with a conventional alphabet. At the station of reception, a large circular disc of the prepared paper is made to revolve uniformly, by simultaneous clock-work, while the iron point, which on every renewal is pressed into contact with the paper, is carried to or from the centre current uniformly by a

screw motion, along a line to the centre of the disc, and leaves traces on the paper as it passes beneath it, in Prussian blue corresponding to the stamped line in the original paper band, and which may therefore be read off at leisure; other preparations, such as that of starch with iodine, potash, &c., may be used for preparing the paper. There is much mechanical ingenuity and skill displayed in every part of this apparatus.

A Council Medal was awarded to Mr. Bain.

BAKEWELL (No. 433, pp. 459-60) exhibits a copying electric telegraph, which is fully described in the illustrated Catalogue, with the method of use, excepting the method of transmitting invisible messages, which is effected by using paper moistened with diluted acid alone, when a deposition of iron from the steel point is made on the paper without any mark, the writing being subsequently made visible by a solution of the prussiate of potash.

A Council Medal was awarded to Mr. Bakewell.

WALKER (No. 430, pp. 458, 459) has exhibited a mode

of insulation of telegraphic wires. The great practical difficulty in telegraphic operations is to overcome the defective insulation consequent on the dampness of the climate. To speak first of the wires suspended in the open air, Mr. Walker has substituted for the old form of cone, to which there were many objections in practice, a large open-mouthed cone, or rather hollow double cone, so constructed that the wire and the cone should be in contact at the smallest possible surfaces; also that, as the place of contact is as far as possible within the cone, it should be as inaccessible as possible to wet; also from its shape, that any wet attaining to the cone would, by mere gravity, run away from the place of contact; also that the part of the cone, where in contact with the wire, should be at the furthest distance from the timber of the pole sustaining all. After suspending the wires, Mr. Walker has the cone covered in with a roof, having sides and ends.

The wires from Red Hill to Shalford, a distance of 19 miles; from Ash to Reading, 19 miles; from Ashford to St. Leonards, 28 miles; and from Tunbridge Wells to Robertsbridge, 15 miles, are all suspended in this way. These lines are remarkable for their perfect insulation and good working order. It was feared that the birds would build nests in the roofs, but such, as yet, has not been the case. This plan involves no additional expense.

1. *In regard to Tunnel Wires.*—The deposit of damp and dirt on the suspension apparatus of Mr. Walker's tunnel wires, on the South-Eastern Railway Company's lines, as first erected for him, caused so great a loss and distribution of the voltaic force, that without some improvement a total obstruction of telegraph business would have ensued, and messages to Dover, instead of passing direct, must have been transmitted through an intermediate station.

About the time that Mr. Siemens, of Berlin, was contriving wire covered with gutta percha, it occurred to Mr. Walker to direct Mr. Foster's attention to that substance, and to request that a specimen should be prepared for him. The result was, that Mr. Foster obtained a patent, of which the Telegraph Company have the monopoly. It was first used in Mr. Walker's tunnels, where, instead of the old mode of suspending, it is now laid in a grooved board covered in. The grooves are ploughed by machinery; the board is prepared with mineral varnish, and is secured close to the tunnel walls, remaining, when once nailed on, in good working order, and in a perfect state of insulation. This grooved board, simple as it is, will doubtless prove a valuable invention, and those who have felt the charge of badly insulated wires will appreciate the improvement. Compared with suspended wires, it is important to the safety of trains and passengers. The old wires have many times been entangled with trains, not only being torn down, but putting the lives of all exposed in jeopardy. Several narrow escapes of this kind have occurred. The last tunnel on the South-Eastern Company's lines, that between Ilgham and Rochester, is now being fitted up with grooved boards; and this board is used on all sustaining walls, of which there are many on the North Kent line; in leading in to stations sometimes down the wall, at other times under the floor. Being prepared by machinery, it is not at all costly.

II. *Compound Needle.*—The first telegraphs made were furnished with long coils and needles. Mr. Holmes introduced the needle, now in general use, in the form of a rhomboid, with a much smaller coil of silk-covered wire. By means of this improvement, legible signals are obtained through longer distances, and can be conveyed very rapidly and distinctly. But the great inconvenience with this needle is the readiness, as we have already mentioned, with which it parts with its magnetism, losing it by little and little during the ordinary use of the instrument, at times suddenly and often totally when lightning discharges occur near the wires. With a view of obviating these inconveniences, Mr. Walker has substituted for it, in the same small coils, an ivory disc, having several short rectilinear needles placed side by side upon it, and at small distances apart. These needles possess all the good qualities of the rhomboidal; but they give

a more dead beat, and are less disposed to part with magnetism. They have not yet been tried in *extenso*; but Mr. Walker has tested them for long periods at important stations, and is now about to use them extensively on account of the serious interruption that has occurred simultaneously in all parts of the country from loss of magnetism. During this summer it was not of unfrequent occurrence to have two or three magnetizers, travelling as rapidly as possible from station to station, to remagnetize; and sometimes before their day's work has ended, demagnetization had again occurred at some stations.

III. *Bell Transmitters.*—This application is not generally employed, and is constructed specially for the chief office at Tunbridge. It is for placing the bell, when one part of the line is in use between London and Dover, on the part or side not in use, so that its ring may be heard, and thereby notice given that the line is wanted. By this arrangement the necessity of cutting short the communication, or rendering it as brief as possible, is indicated.

The bell and needle being on the same wire, this wire is cut at Tunbridge in the three proper places, viz., between London and the bell, between the bell and the needle, and between the needle and Dover, making six ends. These ends are made to terminate in springs, which rest on brass plates, imbed in a wooden cylinder. In one position of the cylinder the springs are connected in the order, London, bell, needle, Dover; so that when talking to Dover, having the line cut off between the needle and the bell, by connecting the wire here with the earth, the bell can be heard to ring, should London send a current along the wire. In the other positions of the cylinder the springs are connected in the order, London, needle, bell, Dover; and similar advantages are experienced in respect to Dover. This plan works well. On the same principle of combination Mr. Walker constructs all his turn-plates, of which he has many varieties; the following is one:—

IV. *Branch double Turn-plate.*—This apparatus is used at junction-stations for putting branch lines of telegraph in communication with either end of a main line. It is constructed by intercepting the branch wires before they terminate in the earth, and by cutting the main wires and providing springs at the intersections. The springs are so arranged that, in the normal position of the drum or cylinder, the terminal stations of the main line are open to each other, and the branch line terminates at the junction-station. In another position of the drum, the London terminus of the line is connected with the branch line, and the wires from Dover end at the junction-station. In a third position of the drum, the Dover terminus is in connection with the branch line, and the wires from London end in the junction-station. This is in daily use at the stations on the line, and acts well.

V. *Lightning Conductor.*—This consists of a small hollow metal cylinder connected with the earth, its purpose being to conduct away the discharge. The line-wire, in its passage from the railway to the telegraph, passes within this cylinder; traversing which it is first presented to the inner surface in the condition of a thick wire, furnished with spurs, whose points are in the closest possible proximity to the cylinder, without being in actual contact; it is then continued on and presented as a short coil of very fine wire, finer, in fact, than that of the instrument coils, wound on a bobbin, the outer convolution of the coil being very close to the cylinder. Thus a better means of escape is presented to the lightning than is to be found in any part of the instrument, consequently it always escapes by this conductor either through the points or by burning the fine wire. As yet no instance has occurred in which these conductors have failed to act, and to preserve the instrument; while instruments in the same office, not thus protected, have on several occasions been damaged.

VI. *Graphite Battery.*—The ordinary telegraph battery consists of plates of amalgamated zinc and clean copper, in cells filled with pure sand, saturated with diluted sulphuric acid. The majority of telegraph batteries are in actual use during a small portion only of each day,

remaining at rest for the remainder of the twenty-four hours, ready for use and in good working order when required. During this time of inactivity there is a continuous slow action between the diluted acid and the copper, whence is produced sulphate of copper, which in its turn becomes decomposed, and the copper released upon the zinc, induces local action, greatly reducing the power of the battery and destroying the zinc, so that it requires to be changed and cleansed more frequently than would otherwise be the case. To obviate this, Mr. Walker sought for a substance that might possess the good properties of the copper-plate, but which should not be acted upon by the acid. The corrosion deposited on the interior of old gas retorts is admirably adapted for this purpose, and he has had it cut into plates by circular saws, worked by steam machinery. He has preserved the history of a 12-plate battery, which was connected up to do telegraph duty, where the waiting-time was very great as compared with the working-time. It was charged in the usual way, with diluted sulphuric acid, on April 5, 1849, and remained efficient till the middle of February, 1851, without having been washed or having had the sand changed. It was supplied with about a dessert-spoonful of acid water twenty-one times during the above period of ninety-seven weeks, and six times with merely warm water. It suffered most from mere evaporation; in some cases it did duty for thirty-four, thirty-nine, and forty days, and in one instance for seventy-seven days, without having been touched. On September 15, 1851, it was dusted and had a little acid water poured in, when it still gave a feeble working current.

**VII. Moveable Studs.**—This is a very simple arrangement, and originated with Mr. Walker. The motion of the telegraph needle is limited within a certain angle by two small ivory studs. In the year 1848 there were so many magnetic storms and other abnormal conditions, that the needles were very frequently deflected in either direction, and often hard up to the studs, so that the power of deflecting in that direction for the purpose of signalling was lost, the needle being already there, and thus the telegraph was rendered nearly useless; indeed, quite so in the hands of inexperienced clerks. To remedy this, Mr. Walker has mounted the studs on a circular and moveable disc, so that in proportion as the needle is deflected abnormally, the studs may be moved after it by the motion of this disc, and the needle, though not hanging vertical, may still maintain its position of equilibrium midway between the studs. This contrivance works well, and the Telegraph Company have adopted it.

**VIII. Ringing Handle.**—This is used at stations where the bell has a distinct wire to itself. It enables an intermediate station to send the electric force in the direction only of the station whose attention it is required to call. This improvement is Mr. Walker's, as are also the essential details of the apparatus; before the introduction of which it was found difficult to keep the circuit good. The line wires are cut between the ringing key and the bell, and strong springs are inserted, which press on brass studs and keep good the circuit when the apparatus is in a state of rest. To the handle is attached a moveable cylinder, furnished with two strong studs in proper connection with the respective poles of the battery. By moving the handle, one of these studs, and consequently one pole of the battery is put in connection with a strong brass boss, connected by a wire with the earth, and the other stud, according as the handle is moved to the right or to the left, raises the spring on either side the bell, and sends the current up or down the line, as the case may be. This arrangement is used throughout the South-Eastern Company's lines, and works well.

A Prize Medal was awarded to Mr. WALKER. **ALLAN'S Patent** (No. 201, p. 421) consists of a circular alphabet, arranged in a sloping position, with an alphabet of a pointer, which by a handle is brought round to by a single revolution; at the same time it makes, breaks, or reverses the current. By this means the pointers carried on the second of telegraph dials are made to indicate the letter at distant stations.

The chief feature is the form and disposal of the many-poled permanent magnet which works the ratchet-wheel arrangement, thereby giving motion to the pointer or index of the telegraph. The power in this instance is created by two electro-magnets, having their poles projecting between the arms of the many-poled permanent magnet, each pair of arms being so magnetized as to act collectively in conjunction with the poles of the temporary magnets; by this means the frame acting upon the ratchet-wheel is made to alternate in coincidence with the changing of the current, and so cause the axis of the index-hand to rotate.

To impart a rapid movement to the index-hand, the current changer is formed of three metallic discs, insulated from each other, and so arranged as to the number of letters on the dial-plate, that the current is made, broken, and reversed accordingly, and causing the index-hand to pass round at once to the letter required, with great rapidity.

Allan's needle telegraph consists of four electric cylinder coils, placed between the arms of a many-poled magnet of four pair of arms; each arm of each pair is magnetized so as to possess the same polarity; thus when the current passes through the coils, the combined magnet is attracted or repelled in either direction, according to the movement of the current, thereby giving deflection to a needle with great rapidity and precision.

The system developed by these improvements consists in forming magnets out of one piece of steel, with any number of poles required, and placing cylinder-coils, or electro-magnets, between the poles, thereby not only obtaining a much greater amount of magnetic power within a small compass, but also a greatly diminished resistance to the electric current: as each turn of wire in each coil is so placed that the current passing is within effective influence of a magnetic pole, none is lost, whilst the length of wire, and consequent resistance is greatly reduced; the action, too, being direct, likewise prevents the loss or waste of the current power.

The great advantages gained by these combinations are shown by the fact of there being surplus power sufficient to overcome the friction of the ratchet-wheel arrangement, without the assistance of weights or machinery, also with as little battery power as the common needle telegraph now in use.

A Prize Medal was awarded to Mr. ALLAN.

**DERING** (No. 436, p. 460) has exhibited an electric telegraph. Mr. Dering suspends his indicating magnet (which is deflected) not by the simple action of the current, but by coil-magnets on either side, so as to have its centre of gravity below the points of suspension: either by elastic bands, by the attraction of a permanent magnet, or by such an adjustment of a straight bar, or pair of watch-springs, as shall give it a decided tendency to a vertical position when not under lateral influence.

Mr. Dering has also exhibited an apparatus for conveying secret signals without extra wires; signals which shall be read off only at given localities without passing along the whole line included in the primary wire. This he has accomplished by placing at each station a step-by-step revolving disc, included in the primary line of wire, but so arranged as not to be set in rotation except by a galvanic force greatly superior to that which makes the ordinary signals, or, when only currents in one direction are used for these signals, then, by the reverse current. This disc, being brought at every station to correspondence in point of position with its position at the initial station, is made by a system of non-conducting interruptions to the continuity of its circumference to establish a break, according to its position, cross connections, or short cuts by which the signal current can pass (and therefore will pass) from one point to another of the primary line of wire, without running through the length of wire constituting the local working coil of the station, so that the working of the telegraph at that station is temporarily suspended, the electricity finding for a time a shorter and easier passage. Besides this ingenious contrivance, Mr. Dering has exhibited modes of preventing the disturbing action of atmospheric electricity and the destructive effects of lightning.

Mr. Dering considers—

I. The steel best suited for the electric magnets is that employed to form the balance-springs of watches.

II. As regards the mode of suspension for single telegraphic needles, instead of suspending the needle in a round hole by a round pivot in the middle, or nearly so, Mr. Dering finds it in all cases better in practice to use a triangular-shaped hole at the upper end of the needle, with a round pivot on which to suspend it. This allows freedom of motion quite sufficient, whilst it entirely checks vibration. The instrument on this principle exhibited, shows the great rapidity in the change of place of the needle combined with freedom from vibration.

III. By a peculiar arrangement of coils for producing motion in telegraphic needles, with the same number of convolutions, the total length of wire is lessened, and thus the battery force required is diminished.

IV. In the apparatus for the transmission of secret messages, by throwing stations out of the line of communication, there is a means provided of instantly restoring the revolving discs at any moment desired, and from any position, to the starting point.

V. In case of a telegraphic needle being deflected by the aurora borealis, or other slight atmospheric influence, Mr. Dering places in the circuit of the line-wire a battery of sufficient force (regulated by the number of galvanic elements) to counteract the disturbing influence, and thus restore the needle to its ordinary position of equilibrium.

VI. An instrument for protection against atmospheric electricity is also exhibited, as described under the eighth head of specification in Mr. Dering's patent. In this the size of the balls may be increased to any extent, provided their distance from the opposed plates be in a proper proportion diminished. This would prevent the chance of the destruction of any part of the safety apparatus.

The Jury considered Mr. Dering as deserving of very Honourable Mention for the great ingenuity he has displayed in these inventions.

BRETT (No. 422, p. 455) has exhibited a patent electric telegraph alarm-bell, bell-handle, and battery. The various letters or numbers represented on the face of the dial of the electric telegraph are made by the motion of either or both of the indicators, the number of which motions for each letter or number is defined by the figures on the centre of the dial, commencing at all times with the indicator on the side next the letter or number, and when both indicators are used, finishing with the opposite one. The helices being double and of a circular form, the greatest amount of electricity is concentrated in their centre, and the magnet being in the form of a ring or horse-shoe, suspended in the centre of the helices, its poles are acted upon by the maximum amount of force, by which great certainty is attained, and the magnet is deflected to the right or left according to the direction taken by the current. The poles of the magnet being equidistant from the earth, the magnet is rendered static, and is not affected by terrestrial magnetism.

LITTLE (p. 455) suspends a common sewing-needle within a tube containing alcohol by means of a permanent magnet at the upper end, so that it can deflect without friction, and does not jar against the electro-magnetic coil on either side which deflects it, while the permanent magnet keeps up the magnetism of the needle.

ALEXANDER (No. 426, pp. 455, 456) exhibits a model of an electro-magnetic telegraph, described in the Illustrated Catalogue. It is interesting as representing an early development of the idea of a needle telegraph. It has 30 line-wires, 30 galvanometers, and 30 needles; the latter carrying each a paper-screen, which, when moved, unveils a letter, &c. The galvanometers are not calculated for actual work in real practice; and, as only one wire is used as a return wire, common to all the galvanometers, there must follow a distribution of electricity among the rest of the wires, fatal to real signalling. The earth is the return circuit in all practical plans.

SMITH (No. 424, p. 455) exhibits a comic electric telegraph. This is a three-wire telegraph, and the author considers that, by three combinations, all that is necessary in telegraphic communications can be performed.

McNAIR (No. 421, p. 455) exhibits specimens of electric-conducting wires for subaqueous purposes. The process of making this wire is by first placing a coating alternately of gutta-percha, or caoutchouc, and braiding of cotton-thread, till the cumulation is of a given thickness: after which it has an outer coating of gutta-percha, and is then placed down a hollow mandril, and by means of a great hydraulic pressure, a lead covering is placed around it, embracing it so firmly that the whole is one compact body. This article seems to answer its purpose well; and, although there were many specimens of subaqueous wire in the Exhibition, yet, for the most part, their base is Mr. McNair's wire.

WHISHAW (No. 419, pp. 454, 455) has exhibited well-made gutta-percha tubes, furnished with ivory mouth-pieces, useful for talking across rooms, or in a railway carriage, or for deaf persons: an early specimen of gutta-percha tubing and lathe-bands: submarine, insulated electric copper wire, covered with gutta-percha, braided with linen, and painted or varnished. These specimens would not bear the wear and tear incident upon the knocking about they would meet with. A long wooden box, to be used as a battery protection; a private code box—this is a box with a sloping front perforated with slits; letters are arranged vertically on the side, and horizontally on the top. Within the box are as many rollers as there are slits in front, around which are wrapped long bands of paper, each having a communication printed thereon, and repeated many times. The end of each band projects so that it may be easily drawn out. By looking at the two letters corresponding with those sent from the Telegraph Office, the communication is at once discovered. A model to illustrate the hydraulic telegraph. The hydraulic telegraph was invented in the year 1837, and from that time there have been several modifications; some have been furnished with floats and indexes carrying letters, &c., some with floats and metal-rods, which, on being either elevated or depressed, point to letters, &c. A reservoir for the supply of the water, and a tank for the waste are required at each station. In the model exhibited, a syphon-tube shows the application of the water itself, which rises and falls in the tubes by opening or closing the respective cocks. Patent glass tubes, to insulate and protect the wires of the electric-telegraph when placed under ground. The use of these would be found to be expensive, and probably, hazardous.

Patent multi-tubular pipes, of glazed earthenware, well-made; their use is to insulate and separate the wires of electric-telegraphs when placed under ground. Probably these would be perfectly insulated with gutta-percha wires, but, if broken, there would be some difficulty in replacing them. The desiderata are, great durability and great accessibility.

Wrought-iron pipes, with ball and socket joints. The length of each pipe is 2 feet, and allows an inclination of about 10 degrees, forming a subaqueous chain for protecting electric telegraph wires when under water. This arrangement seems to be good.

This completes the British portion of the exhibition of electric telegraphs, and from it a very good picture of the English systems of telegraph is presented. One out of the only two specimens which have been sent from abroad is that of Siemens and Halske, Prussian system, and which we proceed to describe:—

SIEMENS and HALSKE (Prussia, No. 310A, p. 1067). The telegraph exhibited by these inventors is extremely ingenious, and the construction and details are very good. It differs essentially from all others that have fallen under our notice, in that signals are made by arresting, instead of by causing, the passage of electric force. It consists of three parts,—an alarm, an indicating dial, and a printing arrangement. The force is derived from voltaic batteries. Daniell's constant battery is employed, twenty-five pairs of which, at each station (for the batteries at both communicating stations act in concert), are said to act through about 250 miles of wire. The force, in all cases, is made available by means of electro-magnets. And first, in respect to the arrangement, when no communications are passing, but the stations are each in a condition to receive notice that they are required to attend.

The bells alone are left in the circuit. When a current passes along the wire, the keepers of the electro-magnets, which are on one arm of a lever, are attracted, which causes a small hammer on the other arm of the lever to strike a bell. The clerk who desires to call attention turns his own bell out of circuit, by moving a lever, and, at the same time, turns his battery and his telegraph instrument into the circuit, and then leaves them. This allows the electric force to have free course, and the distant bell to ring; but the electro-magnet of the alarm is so adjusted that the circuit becomes broken the moment the armature leaves its normal position, which it does by the attraction of the magnetism: the magnetism, therefore, ceases with the cessation of the current, and the armature returns again to complete the circuit; and so on, alternately, producing a succession of blows upon the bell. During this time, the telegraph instrument of the first station, although in the circuit, is perfectly inactive; being so arranged that its electro-magnet is much less sensitive than that of the alarm, its armature requiring more electric force, or more time to acquire motion, so that the circuit is broken by the action of the alarm before the telegraph has been able to move. When the sounding of the bell has gained attention at the distant station, the officer in charge there turns his alarm out of circuit, and introduces his telegraph instrument and his battery. There are now in circuit a battery, and an instrument at each station, which are so arranged that the two batteries combine to produce a current in one constant direction, and, hence, both act simultaneously on both instruments.

The instrument presents a circular dial, around which are engraved the letters of the alphabet, or other conventional signals, and is furnished with an index, which, under the conditions above named, continues traversing the circle at the rate of about thirty times per minute. The two (or more, as the case may be) instruments act precisely in concert, which is thus accomplished:—

The armature of the electro-magnet carries a lever, at the end of which is a claw; that advances one tooth of a ratchet-wheel (mounted on the same axis with the index) at every attraction. But this armature breaks the circuit at each attraction; and the magnetism ceasing, it is returned to its normal position by the action of a slight spring, again to complete the circuit, and to draw on one more tooth of the wheel, and cause the index to advance, and so on. All things being in order, the alternate making and breaking of the circuit are simultaneous on each instrument, and the indices of each point to similar letters at the same time. In order to turn this arrangement to account, the dial is surrounded by a circle of studs corresponding to their respective letters. On pressing any one of these down, it impedes the progress of the ratchet-wheel just at the time when the circuit has become discontinuous, and no current is passing. The index, therefore, of each instrument rests at the letter in question, and continues its course only when the stud is allowed to return, and the wheel is liberated.

With the following additions this instrument becomes a *printing telegraph*. The ratchet-wheel is furnished with radii, consisting of springs, each having a type-letter at the end, directed upwards. In the revolution of the wheel, these types pass between a hammer below and a blackened cylinder above, and between the type and the cylinder passes a band of paper. The hammer is on one arm of a lever, the other arm of which carries the armature of a supplementary electro-magnet, which magnet is in the same circuit with the magnet of the indicating instrument. A current passes through the two simultaneously, but is so instantaneously cut off that the magnetism has not had time fully to develop itself and to attract the armature; but the act of depressing the stud, which causes the index to rest for a moment at a given letter, is contrived to keep the circuit of the printing magnet complete during the same interval, and so to allow the full development of its magnetism, and to cause the attraction of its armature. The type-letter in question is at this moment between the hammer and the paper band. The armature, being powerfully attracted, causes the hammer to strike a smart blow upward, and then

to press the paper against the blackened cylinder, which prints the form of the letter. Letter after letter is thus printed, and a blank is touched at the end of each word. When the blanks are struck, the hammer, meeting with no resistance, moves a little further, and enables a lever attached to it to reach a bell, which was beyond its former limit, and thus the sound of a bell is heard at the end of every word. At the same time that the hammer strikes a letter it breaks the circuit of the printing magnet, and thus liberates itself, and returns to its normal position the moment its work is done.

The lever that carries the hammer is likewise provided with arrangements for advancing the paper the width of one letter as it returns to its position of rest, so that the letters follow in due succession; it also advances the blackened cylinder in the direction of its axis, so that it shall not become exhausted by always printing from the same surface.

There are other arrangements provided for facilitating the transmission of electric force to long distances, and for overcoming some of the difficulties that occur in practice.\*

A Council Medal was awarded for this beautiful system of telegraph.

The remaining foreign Exhibitor—

STÖHRER (Saxony, No. 15, p. 1105), exhibits a magneto-electric telegraph. It is applicable to the ordinary use of telegraphs. In practice the hand always turns the same way. Attached is an alarm bell, which is readily put in and out of connexion.

A Prize Medal was awarded to Mr. STÖHRER.

#### *Domestic Telegraphs.*

BURDETT (No. 425, p. 455) has exhibited a domestic telegraph, designed to supersede the use of bells in mansions, club-houses, hotels, and large public buildings. The machine itself presents a smooth surface or dial, with various numbers indicated upon it. Every room in the establishment with which it is in connexion, being numbered, is furnished with a wire attached to the corresponding number of the machine, which has a bell attached to itself. On any one of the wires being pulled, the fact is indicated by the striking of the bell, the indicators pointing at the same time to the corresponding number of the room which requires attendance; before doing which, the attendant should replace it, by pressing down the lever at the foot of the dial; but, should several indicators on the face of the dial denote that several wires have been pulled at the same time, the machine is so contrived that he may replace them successively as they are attended to. It is intended to obviate the confusion attendant upon the ringing of a number of bells at the same time, a source of great perplexity to the servants; as the bells having ceased ringing, they are deprived of the means of knowing in what part of the house their attendance is required. The machine is by no means unsightly, and is far less expensive than the ordinary sitting up with bells.

REID (No. 427, pp. 456, 457) has exhibited a pair of electric telegraphs, adapted for the use of hotels, taverns, public gardens, &c.

Also, another pair, for railway boards, public companies, manufactories, &c.

A pair of electric telegraphs for domestic purposes, adapted to gentlemen's dressing-rooms, libraries, or ladies' boudoirs, &c.

Also an electrical apparatus for ringing bells in large mansions, hotels, &c. To be brought into immediate action by pulling a cord or lever, as with common bells. This instrument is designed to act at great distances with ease and rapidity.

WHISHAW (No. 419, pp. 454, 455) has exhibited a domestic telegraph. The dial, which has an index hand affixed to it, has also engraven upon its face a number of short sentences or written orders for requisites, such as are likely to be called for at the establishment to which the telegraph belongs. The index points to any one of these sentences as required, the communication

\* For a full description of Siemens and Halske's telegraph, with plates, see Schellen, *Der electromagnetische Telegraph*, Braunschweig, 1850.

being established by means of wires and cranks in connection with a clock movement.

BROOKS (United States, No. 222, p. 1450) exhibits a bell telegraph for the use of hotels, &c., consisting of one bell, with a series of springs; it seems well adapted for its work.

HOWLAND (United States, No. 486, p. 1465) has exhibited a bell telegraph for the use of hotels, dwelling-houses, steamships, &c., and is designed to avoid the complication of bells necessarily employed in large establishments. Each signal on the dial of the instrument is distinct, and remains fixed until relieved by an attendant. It may readily be attached to the usual arrangement for bells. It is ornamental and requires but little space.

#### *Chemical Apparatus.*

A very small number of manufacturers have contributed to the Exhibition, and, with the exception of QUENNENSEN (France, No. 1683, p. 1257), and STAFFEL (Russia, No. 148, p. 1371), no great preference can be given to one or the other of the principal Exhibitors. It may, however, be mentioned, that, more or less, the chemical glass and china apparatus, made by German manufacturers, have been exhibited by the majority, which indicates its adaptation to practical use, as might be expected from its greater lightness and durability.

No new invention, except that of Mr. Staffel, nor any new application of known construction of apparatus, is mentioned.

KNIGHT and SONS (No. 453, pp. 462, 463) exhibit a chemical cabinet, containing apparatus for laboratories, graduated cylinders, jars, blow-pipes, an improved bellows, pneumatic troughs, chemical tests; lamps, retorts, and other glass articles; apparatus from iron and earthenware, arranging furnaces, mortars, &c., being a complete set of articles in daily use by the practical chemist.

This cabinet is intended to combine usefulness with economy: it is proposed that such cabinets should be fitted up with apparatus and tests for the agriculturist, the analyst, the commercial man, and the student, with the prices attached to each article, so that the amount of the first outlay being under control, the ultimate expense may be known with certainty, and the difficulty of selecting appropriate and useful apparatus avoided; as well as the necessity of devoting an entire room to the purpose. This cabinet promises to be highly useful.

A Prize Medal was awarded to Knight and Sons for their chemical cabinet.

Knight and Sons also exhibit a chemical furnace on the same principle as that of Dr. Black, which is constructed of stout sheet-iron lined with fire-bricks, and is applicable to nearly every purpose for which a furnace is required; one sand bath, stoppers, crucibles, muffles, rings, &c.

Knight and Sons also exhibit a galvanic battery, according to the arrangement of Daniell, consisting of a series of six cells, each holding a copper cylindrical vessel, to be filled with a solution of sulphate of copper, in the centre of which is a porous tube, filled with diluted sulphuric acid, and containing an amalgamated zinc rod; also a battery on Grove's arrangement, consisting of a series of six cells, each comprising a glass vessel, containing an amalgamated zinc plate, to be filled with diluted sulphuric acid, having in the centre a flat porous cell, with a platinum plate, and filled with nitric acid; also another battery on Green's arrangement, consisting of a series of six cells, each comprising a glass vessel, containing diluted sulphuric acid; to each cell is a series of three plates, the centre one being of platinised silver plate, and the others amalgamated zinc. These plates are connected to one rod and can be easily raised out of or lowered into the liquor.

A galvanic battery, on the Maynooth arrangement, consisting of a series of ten cells, each being a cast-iron trough, filled with diluted nitric acid. In each cell is placed a porous cell, charged with diluted sulphuric acid, containing an amalgamated zinc plate.

A galvanic battery, consisting of cells formed of gutta-

percha filled with sand, saturated with diluted sulphuric acid, each cell containing a copper plate, and one of amalgamated zinc.

GRIFFIN (No. 457, p. 463) exhibits graduated glass instruments, applicable to the examination of carbonate of soda and carbonate of potash, of all degrees of impurity, ammonia, sulphuric acid, muriatic acid, acetic acid, and vinegar of all strengths, bleaching powder, and bleaching liquors generally; the graduation of these instruments is executed on the principle of assigning a fixed volume to the atomic weights of each chemical compound when in solution, and so producing a series of equivalent test liquors. The standard is made on the consideration that 100 grains of oxygen, in a deci-gallon of solution (being in the proportion of 1,000 grains in a gallon), at the temperature of 62° Fahr., produce a solution of 100', which represents a quantity of any chemical substance equivalent to 100 grains of oxygen, or its atomic weight expressed in grains, contained in a deci-gallon of the solution.

Thus—

503.38 grains of hydrate of soda,  
667.34 grains of anhydrous carbonate of soda,  
1792.13 grains of crystalline carbonate of soda,

dissolved respectively in water, so as to make a deci-gallon of solution at 62° Fahr., are of the same chemical strength.

In like manner

643.19 grains of anhydrous acetic acid,  
455.13 grains of anhydrous muriatic acid,  
501.165 grains of anhydrous sulphuric acid,  
2028.64 grains of nitrate of silver,

brought into aqueous solutions of the above bulk at 62° Fahr., are all solutions of 100° of chemical strength. The extreme convenience of this system carried out in a laboratory in respect to the saving of time, thought, and calculation, and its power of securing uniformity of manipulation, must be obvious to every chemist.

The graduation of all the glass measures applicable to these investigations, as well as all others exhibited by Mr. Griffin, is exceedingly accurate and good, the divisions from 10 to 10, being performed by Ackland's graduating machine, which gives correct aliquant parts. The unit of measure, to which the small measure, called pipettes and alcalimeters, is referred, is termed by Mr. Griffin the *septem*, by which is meant the bulk of seven grains of water, at the temperature and under the barometric pressure at which the imperial measures are regulated: 1,000 septems make a deci-gallon, corresponding to 1 lb. avoirdupois of distilled water, and the tenth part of an imperial gallon of water. The septem, therefore, is identical with the milli-gallon.

Mr. Griffin exhibits a set of decimal weights and measures founded on the imperial gallon and the 1 lb. of 7,000 grains.

This Exhibitor, in addition, has given a rich collection of objects, for the most part similar to those exhibited by No. 453, consisting chiefly of apparatus for making assays with the blow-pipe, mineralogical boxes, a large collection of graduated glass apparatus, applicable to various purposes, boxes fitted with chemical tests, alcalimeters, saccharometers, areometers. In the arrangements made by Mr. Griffin for special purposes, everything necessary has been included, to the exclusion of all else, with especial reference to economy and convenience.

A Prize Medal was awarded to Mr. Griffin.

EDWARDS (No. 438, p. 461) has exhibited retorts, phials, and capsules, covered with an electrotyped precipitate of copper, to protect them against cracking by heat; all these articles are good. The covering of glass vessels with copper is not, however, new; but its use would appear to be very little known in England.

The Jury considered Mr. Edwards deserving of Honourable Mention.

IBBETSON (No. 459, p. 463). Blowing apparatus, constructed with two circular bellows, for the purpose of a continuous blast.

STATHAM (No. 456, p. 463). Boxes fitted with chemical tests, in various sizes, pneumatic troughs, &c.

BAKER (No. 396; pp. 451, 452) exhibits a saccharometer and lactometer; but it is to be remarked, with respect to the former instrument, that the optical analysis of sugar surpasses all other modes.

COFFEY (No. 454, p. 463) exhibits chemical apparatus. In a few square feet are comprised the means of performing some of the most important and troublesome operations of the laboratory. It contains a still (or steam-boiler), with sets of moveable pans for decoctions, extracts, evaporations, steam-baths for retorts, stills, &c., drying-closet, a condenser for steam, and worms for other stills, the chamber containing them acting also as a stove and condensing tube. The temperature can be regulated with great exactness, by means of steam-cocks and valves. An improved feeder, a steam-gauge and thermometer, a safety-valve and alarm, are attached to the boiler.

JOHNSON and MATTHEY (Class I., No. 477, p. 161) have exhibited palladium crucibles and capsules. The use of palladium for this purpose has many advantages. Its infusibility, though not so great as that of platina, is such as to enable it to resist the greatest heats applied in all ordinary chemical operations, while it is not subject, as platina is to a considerable extent, and gold, in some degree, to be attacked and corroded by the caustic alkalis at high temperatures. It is much less fusible than gold or silver, and, like the former, resists the action of all acids. For this valuable accession to the list of chemical utensils a Prize Medal was voted.

[It may not be irrelevant to the subject of this report, to suggest as worthy the attention of chemists, the practicability of coating, by galvano-plastic processes, the interior of clay or plumbago crucibles with films of platina, palladium, gold, or even silver (as the use to which they are to be applied may require), of sufficient thickness and cohesion to withstand a moderate amount of mechanical abrasions, and to intercept the action of saline matter in fusion on the crucibles. Much of the original cost, both of material and fabrication, would thus be saved, and the material might be recovered by acids from the worn-out or broken utensils.—J. F. W. H.]

HORNE, THORNTWALTE, and WOOD (No. 220, pp. 434, 435) exhibit a galvanic machine for medical and other purposes, with a case of instruments for its application. The novelty of its construction, and that upon which its utility depends, is, that the current of electricity produced should be of considerable intensity, and flow in one direction only. It is composed of one coil of stout insulated copper wire. A Smee's voltaic battery, with an arrangement for lifting the plates out of the acid when not in use; and a balance galvanometer, for indicating the strength of galvanic currents by means of grain weights.

HEADER (No. 439, p. 461) has exhibited a galvanic machine, with a graduated regulator employed to administer galvanic electricity. It is intended to regulate the intensity of the shock by means of two moveable indices; that on the left by advancing over a graduated arc produces equal increments of power, that on the right by moving over an arc which subdivides the increments of the first index into four parts, makes the advance from one extreme to the other gradual. The difference of construction consists in the proper adjustment of the length and thickness of the generating primary coil to the electro-motive force of the battery, by which the battery surface is much reduced, and a higher degree of magnetism produced in the iron core. The instrument is compact, the bottle of dilute acid being contained in the box of requisites. The high magnetic power permits the use of strong springs which vibrate rapidly: the great range of power is also equally divided. It is the invention of Mr. Header, of Plymouth, and is intended for the use of private families. It may be mentioned that a difference of construction has been resorted to for the purpose of increasing the attractive power by means of a small iron rod in the centre of the core, which is employed to exert a more powerful attraction upon the iron armature of the spring, the shape of the armature itself being peculiar.

TAYLOR (No. 466, p. 464) exhibits a pneumatic battery for igniting gunpowder in blasting operations.

NUNN (No. 371, p. 450) exhibits a hydrometer, capable of ascertaining the specific gravities of all fluids, its range including 0.6 to 2.0. The point of most interest in this instrument consists in the being able to insert certain weights with the instrument below the centre of gravity, thereby rendering its uniform bulk of any specific weight that may be required. By this means considerable accuracy and efficiency are obtained.

LYONS (Class VI., No. 203, p. 291) exhibits several batteries, and claims improvement for his introduction of wood instead of porous cells, which by rendering the deposition of copper more regular in its action, and more constant in its deposition, constitutes an arrangement by which no copper is lost. In consequence of the action of the sulphate of copper being limited to the surface of porous cells, holes were made in the cells, so that the solution becoming acidulated, acted upon the copper: Mr. Lyons, to obviate this, introduced a gutta-percha tube, perforated with holes, and found the copper clear and equal throughout, also the solution of equal strength both at the top and bottom.

The principle here exhibited is that of economizing the battery power.

Mr. Lyons has also introduced methods by which he makes the usual waste available for battery power, by having two cells of gutta-percha, the one fitting within the other, charged with aquafortis; by the introduction of plates of iron on either side, with zinc in the centre, and suitable arrangements, he saves the oxide of copper by its being thrown down. Mr. Lyons has the merit of arrangements whose objects are constant and regular action, cheapness, and suitability to the performance of all that to which electro-magnetism is usually applied.

QUENNESSEN (France, No. 1683, p. 1257). This exhibitor stands first in the exhibition of chemical apparatus, having exhibited a platina alembic for sulphuric acid, containing 250 pints, made in one piece, without seam or solder; also long platina tubes, made without seam, besides crucibles, capsules, &c., all of which are executed with the greatest care, and appear to be of the most finished and exquisite workmanship. Among the articles in platina exhibited by M. Quenessen is an apparatus for the distillation of hydrofluoric acid, of a very complete and perfect kind. A Council Medal was awarded to M. Quenessen.

CHUARD (France, No. 123, p. 1177) exhibits a gazoscope, an apparatus so constructed as to indicate the presence of hydrogen gas, when in an atmosphere containing only  $\frac{1}{100}$ th part of this gas, that is to say, 1 part of gas to 179 of atmospheric air.

In the year 1843, several engineers were appointed to test the gazoscope, in the coal-mines of St. Etienne, and they reported favourably upon its efficacy in preventing explosions of all kinds during the time of trial, viz., during the months of October, November, and December, 1843. According to Sir Humphry Davy, the proportion necessary to an explosion is about  $\frac{1}{14}$ th; and, consequently, if the presence of so small a portion as  $\frac{1}{100}$ th can be shown, its presence would be made manifest long before an explosion could take place.

M. Chuard also exhibits a new safety-lamp, which has been made at the expense of the Board of Health at Paris, for the use of establishments containing spirits, essences, ether, or any kind of volatile and inflammable substance. It possesses the advantage of having no wire gauze and is filled by a tube. It extinguishes itself when the gas becomes explosive, and is inexpensive. The construction of this lamp is very ingenious, and the Jury regret (it not having been patented) their not being at liberty to describe it.

M. Chuard also exhibits a lamp for chemical purposes, &c.

The Jury awarded the Prize Medal to M. Chuard for his safety-lamp.

BONNET (France, No. 1096, p. 1230) has exhibited an assay furnace and a small assortment of crucibles of white clay. Also a small melting furnace, remarkable for the facility with which it can be taken to pieces and cleaned.

DEYEU (France, No. 476, p. 1200), has exhibited a large and complete assortment of utensils of the same description.

LEMOLT (France, No. 303, p. 1191) has exhibited a galvanic battery, patented in France and England, in which zinc is combined with a preparation of carbon agglutinated.

KAPPELLER and SON (Bavaria, No. 28, p. 1099) have exhibited black-lead crucibles, for melting gold, silver, iron, steel, &c. These crucibles have a high reputation for supporting with security the highest temperatures, such as are requisite for smelting iron, steel, &c., and which is due to the introduction of a fire-proof strengthening substance. They are also very cheap, a crucible to carry 100 marks' weight, being sold for four shillings free from Rotterdam. The Jury award Honourable Mention to these crucibles, &c. (Prize Medal awarded in Class XXVII).

SEEL, jun. (Prussia, No. 483, p. 1078), has exhibited a remarkably complete and beautiful steam apparatus, fitted for chemical and pharmaceutical purposes, with still, digesting, and evaporating vessels, and cases for drying and filtration, at single temperatures, in German silver, and which may be considered one of the most complete things of the kind in the Exhibition. A Prize Medal was awarded to Mr. Seel.

ARNOLDI (Prussia, No. 778, p. 1093) has exhibited a good assortment of chemical apparatus, crucibles, evaporating basins, funnels, &c., made of white clay from Thuringen Forest, much resembling, in appearance and quality, our Wedgewood ware for similar uses. In particular may be noticed the great size of some of the vessels, such as a cylindrical one 2 feet in depth and 18 inches in diameter; also a hemispherical basin, 20 inches in diameter.

GRESSLER (Prussia, No. 654, p. 1096) has exhibited a carbon battery, in which the zinc rods have for their section a rectangular cross to expose a greater surface, and the exterior cylinder is composed of carbon powdered and strongly agglutinated by sugar, it is understood, or other saccharine cement, so composed as to dissolve with extreme slowness.

Dr. REINSCH (Zweibrücken, Bavaria, No. 831) has exhibited a galvanic battery of his own invention, in which a zinc cylinder surrounds one of earthenware full of powdered coke. It is used to excite an electro-magnetic apparatus.

KINZELBACH (Wurtemberg, No. 26, p. 1115) has exhibited a silver hydrometer.

WOLFF (Wurtemberg, No. 13, p. 1115) exhibits various chemical apparatus and graduated vessels for measuring fluids. Honourable Mention was awarded by the Jury to Mr. Wolff for his pharmaceutical apparatus for distilling.

LUIME (Prussia, No. 83, p. 1053) has exhibited a rich collection of pharmaceutical apparatus: lamps of different kinds for cooking, calcining, distilling; gasometers constructed in glass, and japanned zinc areometers, mortars, machine for making pills, platina crucibles, an apparatus in platina for preparing hydrofluoric acid; simple apparatus for ascertaining the quantity of sugar in solution by polarized light; glass tubes and various kinds of apparatus for use in laboratories made at the Zechlin glass works. For this valuable collection of chemical apparatus the Jury voted a Prize Medal.

BATKA (Austria, No. 135, p. 1014) exhibits boxes with chemical tests, lamps, retorts, supporters in wood, alcohometers, various kinds of apparatus made from Bohemian glass, and a test apparatus for beer, after the design of Professor Steinheil, of Vienna. A Prize Medal was voted to M. Batka.

BRANDEIS (Austria, No. 133, p. 1014) has an apparatus for the chemical analysis of beer, invented by Professor Balling, of Prague.

STAFFEL (Russia, No. 148, p. 1371) exhibits an apparatus for assaying precious metals.

This invention of Mr. Staffel is intended to supersede neither the solution by fire, nor the various chemical tests which have been brought to a state of great perfection: it is simply designed for practical purposes,

when neither acids nor fire can be made available. The apparatus is constructed on the principle of *specific gravity*, which has been extended to *specific volume*. The great difficulties to be contended with were, 1st, the elasticity of the air; 2ndly, its temperature; 3rdly, capillarity; 4thly, the closing of the apparatus hermetically; and, 5thly, the furnishing a scale for various weights; but after four years of unwearied study and labour Mr. Staffel overcame these difficulties. The apparatus consists of a glass tube, fixed in a brass case, the bottom of which forms a cylinder, which receives its movement by means of a screw. An annular dial, furnished with a hair, for an indicator, shows the degrees from 0 to 99, and controls the motion of this screw. The degrees, from 100 and upwards, are indicated on a plate, fixed at the side, which plate stands in connexion with the dial.

The glass tube is closed hermetically at the top with a glass cover, to which is annexed a capsule, a perpendicular glass cylinder, and two brass bars, serving as a scale.

By the side of the apparatus is a bar, by means of which the dial is brought to zero, and at the same time the fluid in the cylinder is reduced by means of a handle to the normal point. The object to be tested is then weighed by means of weights adapted to the purpose; after which the object is placed in a grate suspended within the fluid, and the capsule carefully closed. The handle is then set in motion and turned, until the weight, previously ascertained, is indicated upon the dial, while the fluid in the perpendicular cylinder will rise to a degree corresponding with the figure on the dial. The figure thus obtained gives the alloy, the remainder the amount of pure metal. For example, if it be required to test an object weighing 24 grains, it will be necessary to stop the dial-hand at 24, and of the fluid in the cylinder, then 8, the result will be

$$24 - 8 = 16,$$

which will give the standard of the gold.

If the gold be alloyed with silver and copper, which will be indicated by the paleness of the colour, it will be necessary to refer to the brass bar for the purpose of showing the alloy. The differential weights of the alloy between gold and copper, and between gold, silver, and copper, are indicated by various scales.

If the object weigh 39 grains, and the cylinder show 11, then the result will be

$$\frac{39 - 11 \times 24}{39} = 17.23 \text{ proof.}^{\circ}$$

The volume of fine silver or gold is marked . . . F;  
The volume of copper, or any other alloy is marked C;  
The volume of specific difference is marked . . . D;  
The volume of weight is marked . . . 1, 2, 3, &c.

If a fusion of 28 F + 11 C is to be made, the figure must be  $F \Rightarrow C - D$ , of  $F + D = C$ , or  $28 F + 11 C = 39 F + 11 D = \frac{11}{39}$  copper or alloy.

The practical utility of the instrument will chiefly be—

1st. The determining the quantity of gold or silver used in manufacturers' wares from either of these metals, and thereby enabling the employer to ascertain whether the finished article contains the exact amount of metal furnished to the workmen.

2ndly. In ascertaining, if required, the value of a chain, though the gold used in the several links be of a different standard.

3rdly. In previously ascertaining the standard of a fusion, when various sorts of silver, of unequal size and weight, are to be melted together.

4thly. In ascertaining the value of coins with the greatest accuracy and despatch.

#### Fire Annihilators by Chemical Application.

PHILLIPS (Class V., No. 92, p. 222) has exhibited a fire annihilator. This is a portable machine for the immediate production of steam, and carbonic acid and other gases, which, being directed upon the burning matter, is designed to check the progress of the flames more speedily than the usual application of water. It is in form cylindrical, and slightly conical; it varies in size

from 16 by 8 inches to 24 by 12 inches, and is comparatively inexpensive.

For use, it is charged with a composition of powdered charcoal, nitrate of potass, and gypsum, in the following proportions: powdered charcoal, 20; nitrate of potass, 60; and gypsum, 5. These materials are boiled together in water, and afterwards dried in a stove, at the temperature of 100°. The whole is moulded into the form of a brick, down the axis of which penetrates a hollow cavity, for the reception of a bottle, which contains a mixture of chlorate of potassa and sugar, surmounted by a globe of sulphuric acid. The charge so prepared is placed in a cylindrical vessel, perforated in many places, which is itself within another cylindrical vessel, also perforated for the passage of the gases; both these are contained within a double cylindrical receiver, the lower part of which contains a quantity of water. The apparatus is closed by two covers; in the outer of which is an opening for the escape of the vapour. In the centre of the cover is placed a spike, for the purpose of breaking the glass bottle deposited in the cavity of the charge. The spike being forced down breaks this bottle, and the sulphuric acid, falling on the mixture of chlorate of potassa and sugar, causes instantaneous combustion, and spreading over the charge, causes a second ignition at once to take place. The gases thus formed pass through the perforations, and by heating the air in the water chamber, and causing it to expand, forces the water up a tubular passage into the spaces between and around the cylindrical vessels placed each within each; and being thus converted into vapour, mixes with the gases, and escapes by the discharge tube. The discharge forms a dense cloud, which continues until the charge is consumed and the water quite exhausted.

On Thursday, September 26, several gentlemen of the Jury assembled at Battersea Fields to witness Mr. Phillips' fire annihilator in operation. There were present—Sir John Herschel, Mr. Glaisher, Mr. Bowerbank, and Professor Collodon. A rough wooden house, two stories high, filled with planks of wood, shavings, &c., was set on fire, and the doors and windows fast closed, previously to which, a quantity of spirits of turpentine had been poured over the combustibles in the interior, from which in the course of a few minutes the flames were seen issuing from the windows, and on the door being burst open presented an unbroken sheet of flame. The fire annihilator was then brought forward, and the vapour directed into the doorway. The effect was almost instantaneous. The great mass of flame was at once extinguished, and at the same moment dense volumes of smoke were seen issuing from the same place. In the course of a few minutes the fire was entirely extinguished, leaving the walls of the house standing, though considerably charred. Ten minutes after (a few lingering traces of fire to the windward being extinguished with wet mops), the Jury entered without inconvenience; the air within being cool and moist. The experiment, which must be considered as a severe test to the powers of the machine, was considered satisfactory in the extreme. Shortly after, a tank, containing a mixture of tar, shavings, and other combustible matters, was ignited, and afterwards extinguished by one of these machines with equal success; the machine being placed to windward, and the gas thus swept over the burning surface, in a state of most violent combustion, instantly annihilating the flame.

The idea which Mr. Phillips has successfully applied to his fire annihilator was suggested to him by witnessing, some years ago, in the Mediterranean Sea, an eruption from an island, thrown up from a depth of 80 fathoms; he observed that, where the vapour formed by the boiling water, and precipitated upon the lava, came in contact with the flame, the latter was instantaneously extinguished.

The fire annihilator, in its action, may be said to resemble that of a pump drawing water, or the condenser of a steam-engine. The vapour which issues from it enters the building in a highly expansive state, and extinguishes the flame chiefly by the presence of gases adverse to combustion, but partly also, no doubt, by

reducing it to a temperature lower than that at which flame can exist. By degrees, the room being full of vapour, the temperature decreases, and the vapour condensing into water, fresh air enters to supply its place, and renders it possible for men to enter, and complete the work of extinction of the embers. The machine is unattended with any practical difficulties in its use; the mixture of steam and gases may be produced within a few seconds after striking the top for the purpose of breaking the little bottle. The vapour itself possesses the advantage of being less destructive to the unconsumed articles with which it comes in contact, and being also a more penetrative medium than water, is better calculated to act simultaneously upon the innumerable particles of gas which combine to produce flame. It is stated to be perfectly innocuous to human life, which, of course, must be understood to mean during that short time, and in that state of admixture with air in which men have occasion to inhale it.

When we take into consideration the large number of fires which, both by day and night, endanger the life and destroy the property of individuals situated in or near the metropolis, the production of a machine such as that which Mr. Phillips has exhibited, promises to be of very considerable utility. By being provided with one of these, each householder is possessed of an instantaneous means of checking a fire at its commencement, long before any great destruction of life or property could be apprehended. Its advantages on ship-board can scarcely be over-estimated, and are most obvious. The Jury, considering it well adapted in its application to the purpose intended, and being perfectly satisfied with its performance in this instance, have awarded Mr. Phillips a Prize Medal.

WEARE (No. 386, p. 451) has exhibited a fire annihilator, designed, by means of a discharge of gas, to extinguish fire, and prevent the ignition and self-combustion of inflammable matter. As the Jury have had no opportunity of examining the machine, or becoming acquainted with its construction, they are not qualified to decide upon its merits.

#### *a. Meteorological Instruments.*

Considering the greatly increased attention which has been paid within the last few years to meteorological researches upon a systematic plan, a part of which is the using instruments well adapted to the work, it is both surprising and very lamentable to perceive, among the numerous exhibitors of barometers and thermometers, instruments of so ordinary and inefficient a construction, the greater part of them being ill adapted and totally unfit for meteorological observations. In the barometers exhibited, the majority of the makers, in their anxiety to render them elegant and decorative articles of furniture, have paid but little attention to its essentials as a philosophical instrument. Their forms, as exhibited, are various, it is true, not as might be expected with a view to discover that construction likely to give the soundest results, but more, it would appear, to suit the requirements of those who can see in a barometer nothing more useful or important than a piece of household furniture, destined to take its place among the usual appurtenances of a well-furnished hall. This is much to be regretted, the barometer offering—as it does—so wide a field for the exertions of the instrument-maker to fit it for the increasing requirements of the present advancing state of meteorological observation. How disappointing it is to find all their exertions directed to the enshrouding it in a case which, with few exceptions, renders it not only cumbersome and inelegant; but, as typifying the apathy of a large class of instrument-makers to the fundamental principles of its construction, to us most offensive: on the score of inelegance of construction, we may, however, except those exhibited by ELLIOTT and SONS, (No. 320), which are fairly models of chaste design and excellent wood-carving. It would be well for the purchasers of these decorative and ill-constructed barometers to remember that by their adoption and use of such instruments they forfeit all claim to scientific notice, and they should also remember that to the well informed no in-

strument can be so pleasing in appearance as that which, from its construction, is well adapted to its work, and likely to lead to good and important results.

Of thermometers we cannot speak more favourably, the greater part of them being furnished with scales of ivory, a material most unsuited to a graduation of any kind; so much so, that the mercurial tube attached to an ivory scale cannot rightly be called a thermometer. The bulbs of those exhibited are nearly all too large, a defect which necessarily entails a very slow change of temperature. In self-registering thermometers there is nothing new, and no attempt has been made to improve the working of the instrument, either by the introduction into the maximum thermometer of a piece of enamel, as a substitute for the steel index, or by any other means. Very few of the tubes of the thermometers exhibited are sunk in the scale, so that the column of mercury may be in the same plane as the divisions, or the back part of the tube cut away to attain the same object; and, what is still more to be regretted, very few thermometers in the English portion are graduated on their stems, a method superior to any for insuring delicacy of graduation and correct readings. These remarks do not apply to the foreign portion of the Exhibition; the exhibitors it includes, however, are few in number, but the instruments generally are pretty good.

No branch of physical science has suffered more than meteorology by the use of bad instruments. Many journals, after years of patient daily labour, have necessarily been laid on one side as useless, owing to the imperfections of the instruments used. To judge from those exhibited, it would appear that as little attention is paid now to the construction of meteorological instruments in London, except by a few makers, as a few years ago, before the commencement of the systematic researches in meteorology at present being carried on by very many gentlemen throughout the country.

It is to be hoped that one of the good results of the Exhibition will be the calling into existence a better class of instruments generally, when not only shall be improved those necessary to physical research, but those also which are in general use by the public. That thermometer is the best whose bulb is small, whose divisions are cut on the stem itself, or engraved on well-seasoned box-wood or on metal. That barometer is the best which is made of brass throughout, and the mercury of which has been boiled in its tube; there should be no plunger, no need of capacity correction; and the most simple means should be adopted for measuring accurately the distances between the surface of the mercury in the cistern and that in the tube, a measurement best attained by means of an ivory point, terminating a brass scale.

The best exhibitor of thermometers in the Exhibition is *FASTRÉ* (France, No. 511). All the instruments exhibited by him are distinguished by delicacy, and are possessed of the essentials of first-rate instruments. The best exhibitors of thermometers in the British portion of the Exhibition are *NEGRETTE* and *ZAMBRA* (No. 160), whose instruments seem to have been made with great care, the divisions being good, and mostly cut on the stems of the thermometers themselves. In appearance there is but little difference between those exhibited by *Negrette* and *Zambra* and those by *Fastré*. The accuracy of division was not examined in either case.\*

We now proceed to speak in detail of the instruments exhibited.

#### *Self-registering Meteorological Apparatus.*

*DOLLOND* (No. 145, p. 426, and see Illustration) has exhibited a self-registering meteorological instrument, which he has called an Atmospheric Recorder.

This instrument registers simultaneously, for any period of time, according to the length of the paper used, the varying pressure of the atmosphere, the changes of tem-

perature and evaporation, the variations in the electrical state of the atmosphere, the fall of rain, the amount of water evaporated from a surface of water, and the force and direction of the wind.

The apparatus is composed of a frame 2 feet by 3 feet 6 inches, and is firmly supported upon four pillars, the sides being strongly braced together. At the distance of 10 inches from either end of the frame, a roller 1 foot in circumference is placed. That near the south end is moved by clock-work, whilst the other acts as a reservoir for the paper; a third, of the same dimensions, is placed near the clock or driving roller, and so arranged as to press upon it equally throughout its length for the purpose of keeping the paper in contact with the driving-roller.

A strong bar is placed near the north end of the frame, upon which the fulcrums of several indicators, about a foot in length, are placed. Those for registering the variations of the barometer, thermometer, and hygrometer, have spring points at their ends; and those for the registration of the electrical changes, the fall of rain, evaporation, and the force and direction of the wind, have pointed pencils. The former are connected with a falling lever, and strike the paper once in every half hour, whilst the latter continuously mark the paper. Near the place of registration each element has its own scale. The indicators are continued somewhat beyond the fulcrums, and are thus connected with the various changes of the atmosphere to be recorded. Between each element on the paper a set of lines is drawn, which form zeros or base lines for the estimate of each. They also give a means of correcting any error caused by the hygrometric or other changes of the paper; on either side of the frame is a marker, which registers the time simultaneously at every half hour.

The barometer used is on the syphon principle, in the shorter leg of which is placed a float, so adjusted as to leave sufficient weight to follow the mercury. The registered scale trebles the actual changes. The apparatus for the temperature consists of ten bent mercurial thermometers, suspended upon a delicate balance. The hygrometer consists of a slip of mahogany cut across the grain, which was divided as follows: being suspended from its upper end, in a cylinder filled with water, a weight of 2 lbs. was attached to its lower extremity, until it was found, by repeated examination, to be completely saturated, and no longer to increase in length. Its whole length was then referred to an accurate scale. The slip of mahogany was then placed beside the pipe of a stove, suspended and weighted as before, until its shortest length was obtained. The difference of the two results being carefully taken, the scale was formed accordingly. In its use it is suspended and weighted as before, in a tube placed outside the observatory, protected from the sun and rain, and has free power to act upon the indicator.

The electrometer is constructed as follows: a well-insulated conductor is placed upon the highest convenient place, from which a wire is brought down to an insulator on the top of the observatory, and from thence to a standard, passing through another insulator to a metal disc, between which and a spring a moveable disc is attached to a glass or insulating arm, in connection with the registering pencil.

The electricity, in the first instance, is collected by means of points. There is a wire, connected with the earth, by which means any excess of electricity is discharged.

The rain-gauge is placed on the top of the observatory, its receiving surface being 1 foot square. The rain is conducted by a pipe into a receiver inside the observatory, and situated under the registering apparatus. An air-float is placed inside the receiver, and connected with a set of inclined planes, each of which is equal to a fall of rain 1 inch in depth. These inclined planes, as they pass upwards, being in connection with the indicating pencil, register the fall of rain.

The evaporating dish is an open cube of 1 foot square, covered with a plate of glass at such an angle as to prevent rain falling into it, yet allowing the air to act freely upon the surface of the water.

\* To examine a thermometer carefully, and determine its index errors at every part of the scale, is very troublesome, and occupies a great many hours; yet every thermometer used for meteorological purposes should be thus examined.

The direction of the wind is shown by an indicating pencil in connection with a vane. The force of the wind is shown by a surface of 1 foot square, being kept in opposition to the direction of the wind by a vane, whose motion is nearly free from friction, every part being counterpoised. On the action of the wind upon the pressure plate, a combination of suspended weights is raised by a chain passing over a pulley in a line with the direction of the wind, and well protected from the weather. The suspended weights are in connection with an inclined lever and indicating pencil. The scale has been determined by experiment. A Council Medal was awarded to Mr. Dollond.

BROOKE (No. 144, pp. 422-426) exhibits photographic apparatus for the self-registration of the dry and wet bulb thermometers.\* It consists of two mercurial thermometers, with very long bulbs; one of them is covered with muslin, which is kept moistened by the capillary action of floss silk, or lamp wick, connected with three cisterns of water.† On either side of the thermometers, and placed near them, is a lamp, the light of which, condensed by a cylindrical lens, whose axis is vertical, falls upon the thermometer stems, and passing through that portion which is above the mercury, affects the paper. As the cylinder revolves, a broad sheet of photographic trace is left, whose breadth varies with the varying height of the mercury in the tube. The boundary of light and darkness thus indicates the height of the mercury in the stem of the thermometer. To know the temperature corresponding to this boundary, fine wires are placed across the thermometer-tube, to prevent the photogenic action of light, and thus transfer sufficient indications of the actual reading of the thermometer. Mr. Brooke also exhibits similar apparatus for the variations of the reading of the barometer. (See Illustrated Catalogue.)

NEWMAN (No. 674, p. 468\*) exhibits a self-registering anerometer and rain-gauge. It consists of a vertical cylinder, actuated by clock-work, and furnished with paper for the consumption of a month.

#### Barometers.

GRIFFITH (No. 331, p. 446) exhibits a barometer of a new construction, giving the observer the power at all times of securing a vacuum above the mercury. The instrument consists of a tube for the column of mercury, with a crook on the top, and bent at the lower part, a joint with a trap placed near the middle of the tube, a stop-cock and a stretcher to close the open part of the glass tube when necessary; a brass bar, carrying two cylinders at the distance of 29.772 inches, and moved up and down by means of a steel screw, with 25 threads to an inch, moveable in a matrix by means of a milled head. The bar carries a pointer for reading to hundredths of an inch, and there is suitable apparatus to read to one-thousandth of an inch.

The purpose of the crook on the top is to trap all the air which may be above the column, and thus to insure a good vacuum.

Mr. Griffith says that no boiling of the mercury is necessary. The instrument, though not tried, and not of very careful workmanship, was considered by the Jury good in principle, and an attempt out of the beaten track to improve the instrument. A Council Medal was awarded.

NEWMAN (No. 674, p. 468\*) exhibits his well-known standard barometer, which is made so as to require as few corrections as possible. The graduated scale which measures the height of the mercury is made of brass, and to it is affixed a brass rod, passing down the inside of one of the upright supports, and terminating in a conical point of ivory; this point in observation is made just to touch the surface of the mercury in the cistern, and the contact is easily seen by the reflected and actual point appearing to meet each other. The rod and scale are made to slide up and down by means of an endless screw and wheel. The scale is divided to 0.05 inch, and the vernier,

which only moves by a slow motion screw, subdivides the scale to 0.002 inch.

At the bottom of the instrument are three screws, turning in the fixed part of the support, and acting on the piece in which the lower pivot of the barometer frame turns for adjustment to verticality. The bore of the tube is between 0.5 to 0.6 of an inch in diameter.

Mr. Newman observes that he has always found tubes boiled under atmospheric pressure to be foul, and that many barometers made with large tubes not boiled look well for a time, but that ultimately air-bubbles are seen to rise to the top and depress the column. These difficulties were to be overcome before filling the tube successfully, the bore of which measured from 0.5 to 0.6 of an inch in diameter. Mr. Newman has adopted the method of filling tubes in vacuo, and boiling them under diminished pressure, at a temperature which obviates all oxidation of the mercury.

ORCHARD (No. 161, p. 429) has exhibited a standard barometer very similar in construction and workmanship to that of Newman; it has, however, in addition a thermometer, placed in front of it, with a bulb of the same diameter as the tube, and there can be no doubt that the temperature of the two equal bulks of mercury will be the same.

VIDI (No. 326, p. 446) exhibits an aneroid barometer of the usual construction. This beautiful instrument, so recently invented by M. Vidi, was rewarded by a Council Medal.

NEGRETTE and ZAMBRA (No. 160A, p. 429) exhibit a barometer arranged to register the highest and lowest readings. It is a syphon barometer, to the longer leg of which, at the distance of 8 inches from the top, is joined a bent glass tube, carried up for 6 inches parallel to the principal tube, and joining it at two inches from the top. The mercury flows freely in and out of this tube, and maintains the same level as that in the larger tube. In this bent tube is placed a small piece of steel, which is kept in position by fine glass springs: as the mercury rises this piece of steel is pushed up, and remains stationary. The lowest readings are indicated by a similar steel index in the shorter leg.

Messrs. Negretti and Zambra also exhibit a barometer with an air-trap glass cistern, to be read off by means of a sliding scale, adjustable to the surface of the mercury by a fine ivory point. The tube and cistern are blown together, and at intermediate junctures are three points, and three small tubes or traps, communicating with each other to prevent the admission of air. This instrument is constructed entirely of glass. A folding barometer is also exhibited, consisting of a tube with a steel stop-cock in the centre, which, when folded up, carries with it the two valves of the tube with which it is connected.

YEATES (No. 332, p. 446) exhibits a barometer, furnished with a brass scale, terminating in an ivory point, and moveable by a screw. The cistern is composed of plate-glass and iron.

Mr. Yeates exhibits also a barometer, furnished with a registering apparatus, which consists of a revolving cylinder four inches in length, around which is paper ruled into thirty-one vertical portions, horizontally into tenths of inches, and numbered from 27 inches to 31 inches. To the receiver a pencil is attached for marking the paper. The ivory point is adjusted to the surface of the mercury by means of a plunger. Mr. Yeates also exhibits a third barometer, furnished with an ivory point, adjusted by a screw acting upon a leather plug attached to the bottom of the cistern. In these three barometers a ready means is furnished of cleansing the surface of the mercury in the cistern, by the withdrawal of a screw plug placed in the cistern near the surface of the mercury.

SOMALVICO (No. 681A, p. 469\*) exhibits a mountain barometer, two upright barometers, three ornamental wheel barometers, &c.

HALL (No. 60, pp. 415, 416) exhibits a meteorological clock, to which is attached a barometer and thermometer kept vibrating by the clock connection, the number of vibrations in a certain time differing according to the variation of temperature in the one case, and of pressure of the air in the other; the number of vibrations is regis-

\* The principle is the same as that described in magnetic instrument, page 280.

† One large cistern will be found to act better.

tered, and from them both the readings of the barometer and thermometer are known.

TRENLETT (No. 163, p. 429) has exhibited a marine barometer in a metal frame, with thermometer, enamelled scales and springs to check oscillation.

ELLIOTT and SONS (No. 320, pp. 443, 444) exhibit barometers carved in walnut-wood, the design representing the four seasons; circular carved wood barometers similarly ornamented; Gothic carved barometers, and two mounted in ebony and gold. It is stated that the mercury in the tubes of all these instruments has been boiled.

BURSILL (No. 673A, p. 468\*) has exhibited a compensatory cistern barometer, in which, by a self-acting contrivance, the mercury is always preserved upon the same level within the cistern, uninfluenced by alteration of temperature or any change in the column of mercury itself.

BROWN (No. 676A, p. 468\*) exhibits a barometer in appearance similar to a water-barometer; it contains two immiscible liquids of nearly equal specific gravities; and their point of meeting, which may be placed at any part of the scale, is indicated by one liquid being coloured. The scale of the instrument, which is arbitrary, is  $7\frac{1}{2}$  feet to an inch of mercury.

Mr. Brown also exhibits two barometers at an exceedingly low price. The readings of a similar barometer were taken for two months commencing from July 15, simultaneously with those of a standard barometer, and was found to act admirably. Before reading it was always found necessary to incline the instrument until the mercury filled the upper portion of the tube: it afterwards descended to its proper level, though the rise at all times took place less freely on account of the smallness of the tube. These barometers are the cheapest in the Exhibition, and are better than any of the ordinary barometers exhibited.

BENNETT (No. 1, p. 406) exhibits barometers of an ordinary construction.

DIXEY (No. 271, p. 438) has exhibited a carved oak barometer, and an ordinary barometer.

HAKEE (No. 616, p. 452) has exhibited two barometers, one of which is that invented by Mr. Brown.

WATKINS and HILL (No. 659, p. 466\*) have exhibited barometers of various ordinary kinds, and Professor Potter's aerometric balance.

GREY and KEEN (No. 138, p. 422) have exhibited wheel barometers mounted according to various designs.

ABRAHAM (No. 140, p. 422) has exhibited a barometer, designed to show, without adjustment, the reading of the barometer. The scale is suspended over a pulley, by means of a counterpoise, the lower end of the scale being connected to a float in the shorter leg of the syphon.

A. H. ROSS (No. 157, p. 429) has exhibited a self-compensating barometer.

PIZZALA (No. 162, p. 429) has exhibited a wheel barometer, constructed with a rack-work motion. The case is elaborately carved in walnut-wood.

GRIMOLDI (No. 159, p. 429) has exhibited a pediment barometer, fitted up in a carved gilt frame.

BOURDON (France, No. 1108, p. 1231) has exhibited several barometers of an original construction. They consist of an elastic flattened tube of metal, exhausted completely of air, and bent very nearly in the form of a circle; they are in this state possessed of the property of expanding, a further separation of the ends being effected when the atmospheric pressure is diminished, a contrary or contracting effect taking place when the pressure increases. A lever is attached to the end of the tube by suitable mechanism, and connected to an index or hand, which traverses a divided dial-plate.

The dial-plate is graduated by placing the instrument with a standard barometer within the receiver of an air-pump, and the points of coincidence determined by varying the pressure. These instruments are applicable for measuring the pressure of the atmosphere, gas, &c., to a range exceeding 500 lbs. on the square inch. They are well adapted for application to steam engines, &c. A Council Medal was awarded to M. Bourdon.

GALY CAZALAT (France, No. 1239, pp. 1236, 1237) has exhibited a manometer. The tension of steam is mea-

sured by the number of atmospheres to which its pressure is equivalent, consequently, by the number of inches of mercury which it will support in a tube by pressure on the surface of a reservoir into which the tube is plunged. The utility of a mercurial gauge is limited in practice by the length of tube capable of being applied, which, if of glass, cannot be safely extended, and if of iron, is very inconvenient, to say nothing of the difficulty of reading. The invention of M. Galy Cazalet is in effect equivalent to increasing in any given ratio the specific gravity of the mercurial column, supported so as to enable a column of any convenient length to counterbalance a pressure, however great. The steam acts only on the sectional area of the rod of a piston, the plunger of which, of much greater sectional area, presses on and so sustains, in the other leg of the inverted syphon, into which it plunges, a mercurial column of sectional area equal to its own. A Prize Medal was awarded to M. Galy Cazalet.

ERICSSON (United States, No. 146, p. 1442) has exhibited an alarm barometer. This instrument is intended chiefly for use on ship-board, and is to be placed in the vicinity of the helmsman, being so constructed that, when the mercury sinks below a certain reading, a hammer is made to strike a gong. The helmsman by this means receives notice of the probable approach of rough weather, and time is afforded for the necessary precautions of taking in sails, &c.

The tube is similar to that of the common barometer, and is much enlarged at the upper end; the lower extremity terminates in a cup, which contains mercury, and is attached to a lever, weighted at one end. By means of the enlargement of the tube, a slight decrease in the reading of the barometer causes a considerable discharge of mercury into the cup, the balance of which is disturbed. This disengages a hammer, which, impelled by a spring, strikes a gong with considerable force. The weight which balances the cup is adjustable upon the lever, and may be so set that notice shall be given of any required reading of the barometer. The lever is marked with divisions corresponding to those on the scale, for the purpose of adjustment.

#### Thermometers.

SIMMS (No. 741, p. 475\*) exhibits two standard thermometers, constructed by the Rev. R. Sheepshanks, who, during the last two or three years, has been more or less engaged in improving these instruments. The divisions are engraved on the stems. The zeros of these instruments, as determined by Mr. Sheepshanks, will be used by Mr. Glaisher in all future observations, and he believes the two instruments, exhibited by Mr. Simms, to be the most correct in the country.

NEGRETTE and ZAMBRA (No. 160A, p. 429) exhibit a standard thermometer, which seems to be good; several very delicate thermometers, with pea bulbs; a delicate dry and wet bulb thermometer; a Daniell's hygrometer; two Regnault's hygrometers, one furnished with black glass cups, instead of silver, designed to avoid oxidation; some thermometers beautifully made, and graduated on their own stems; a dry and wet bulb, with two identical stems close to each other, and united; this form of instrument is useless for practical purposes, but is a masterpiece of tube-blowing; several self-registering thermometers, both of Rutherford's and Sixe's form, &c.

These are the only Exhibitors in the British portion who have sent thermometers with their stems graduated, the only safe instruments for delicate experiments.

A Prize Medal was awarded for the beautiful work shown by these artists.

NEWMAN (No. 674, p. 468\*) exhibits a standard thermometer, the bore of which is stated to be a perfect cylinder, having been examined by the late Captain Kater and Professor Daniell, as well as by Colonel Sabine. Its scale is divided into half degrees; that part of the glass tube which is near the scale is ground flat, and polished, so that the column of mercury is very nearly in the same plane as the scale, by which means the error of reading, so far as parallax is concerned, is avoided. Also, a maximum register thermometer, with a small piece of enamel inserted between the index and the mer-

cury; a minimum and maximum register thermometer, with black bulbs; a Daniell's hygrometer; dry and wet bulb thermometers; a Lind's wind-gauge; and rain-gauges of different kinds.

PHILIPS (No. 411, p. 454) exhibits a maximum thermometer, with a bubble of air, which, by separating a portion of the mercury, causes it to act as the index; an air barometer for coal-pits; and a new electrophorus and cover, to work without making contact by the hand.

WATKINS and HILL (No. 659, p. 466\*) exhibit a dry and wet bulb thermometer, and other thermometers of an ordinary kind.

HARRIS and SON (No. 149, pp. 428, 429) have exhibited a self-registering thermometer.

ELLIOTT and SONS (No. 320, pp. 443, 444) exhibit various ornamented thermometers, and some intended for the pocket.

BENNETT (No. 1, p. 406) has exhibited many thermometers; they are for the most part furnished with ivory scales; the bulbs of those furnished with box-wood scales are too large.

DIXEY (No. 271, p. 438) has exhibited several self-registering thermometers.

BAKER (No. 396, p. 452) has exhibited a thermometer for agricultural purposes.

FASTRÉ (France, No. 501) exhibits probably the best series of delicate and accurate thermometers in the Exhibition; they are distinguished by being nearly all engraved on thin glass stems, and include exceedingly delicate dry and wet bulb thermometers, Regnault's hygrometer, &c. M. Fastré deserves high praise for the production of these beautiful instruments, which the Jury consider worthy of a Prize Medal.

LUHME (Prussia, No. 83, p. 1053). Good thermometers; divisions on glass, and some on paper.

JERACK (Austria, No. 134, p. 1014) has exhibited thermometers graduated on glass, for immersion in acids.

JÜRGENSENS and SONS (Denmark, No. 17, p. 1356) exhibit two metallic thermometers, of a circular form, so arranged as to show the temperature at the time of observation, as well as the maximum and minimum temperatures since the previous inspection. A Prize Medal was awarded to Messrs. Jürgensens and Sons.

#### *Anemometers.*

PHILIPS (No. 411, p. 454) exhibits an anemometer, designed for coal-pits and hospitals, consisting of a semi-circle of card-board, graduated on its edge, and mounted on an axis passing through the diameter of the circle of which the card is the half.

DE HENNAULT (Belgium, No. 183, p. 1157) exhibits a small travelling anemometer, extremely well made, of a simple construction, and furnished with a series of fans, which, by a simple and effective contrivance, may be stopped or set in action almost momentarily. It is intended chiefly to determine the horizontal velocity of the air in a given time. To this exhibitor Honourable Mention was awarded.

#### *Rain-Gauges.*

PHILIPS (No. 411, p. 454) exhibits a rain-gauge, open at the top and four sides, prepared to show not only the fall of rain received on a horizontal surface, but also, by a simple calculation, to ascertain the inclination of the path of the drops and the direction of the rain. The Jury have awarded Honourable Mention to Mr. Philips.

WATKINS and HILL (No. 659, p. 466) exhibit Crossley's self-registering rain-gauge.

BAKER (No. 396, pp. 451, 452) has exhibited a rain-gauge.

#### *Pyrometers.*

ERICSSON (United States, No. 146, p. 1443) has exhibited a pyrometer, an instrument for measuring temperatures from the freezing point of water to the melting point of iron, as indicated by the tension of a permanent volume of air or azote, which is measured by the reading of a column of mercury under a vacuum. The instrument is designed to meet the requirements of the artisan in all works which involve the application of great heat, and

are dependent for success upon an evenly regulated temperature. In the formation of the scale, 32° and 212° have been respectively taken for the points of freezing and boiling water.

The instrument is composed of the following parts:—

A chamber containing mercury, with a flexible bottom, composed of a steel spring, or India-rubber held between steel plates, which may be raised or lowered by means of a screw. Into this chamber a glass tube filled with mercury is plunged to within one-sixteenth of an inch of the base.

Into the mercurial cistern a short glass tube is inserted, connected with a platina bulb by a small passage, the base of which is nearly filled by a silver wire, and a stop-cock. A coupling joint is affixed to the bulb, so that it may be removed at pleasure. The top and sides of the mercurial chamber are surrounded by a cistern for the reception of pounded ice, the whole being encircled by double plates of iron, to be filled with clay or some other non-conducting substance, for the purpose of shielding and supporting the instrument. The screen itself is supported upon a base plate. Two scales form an important feature in the arrangement of this pyrometer, graduated for reading off the height of the mercury in the tube, which reading is determined by the temperature of the medium in the platina bulb.

The graduation of the smaller of these scales reaches only to 700°, but that of the larger is extended to include the melting point of iron. A spirit level for placing the instrument in a vertical position completes the adjustments.

It is to be remembered, that the graduation of the scale is independent of any imperfection in the bore of the tube, and is not affected by the expansion of the bore from heat, the volume for measuring which being permanent and not expanding, affords greater accuracy in the readings at high temperatures.

The pyrometer comes into action where the thermometer ceases to be effective, the air or azote in the bulb of the former enabling it to remain unchanged under extreme variations of temperature, whilst the latter explodes on being thrust into an ordinary flue or vessel of over-heated fluid.

WURM (Austria, No. 137, p. 1014) has exhibited a pyrometer. The instrument is composed of a strong and massive frame of iron with a handle, across which is stretched a moderately strong platina wire, connected with an index in the handle, so arranged that the wire (being always kept in a state of tension by a spring or otherwise), when relaxed by expansion, shifts and marks the amount of extension.

The whole frame being introduced into a furnace or oven, the wire acquires instantly the temperature; the massive frame much more slowly. Relative expansion of the wire therefore takes place, and when this has attained its maximum the index is read off.

The instrument exhibited is adapted to ovens, &c., and is of considerable dimensions.

#### *Tide-Gauges.*

HEWITSON (No. 152, p. 429) exhibits a self-acting and self-registering tide-gauge, every part of which displays good workmanship, and an endeavour to reduce friction or grip to a very small quantity. The teeth of the wheels are carefully made, so that should the rise or fall of the tide amount to the fraction of an inch only, a simultaneous movement of the whole machine follows to that extent. It is furnished with a brass cylinder, the axes of which are of bell-metal, revolving in Y's. The traversing bar carrying the registering pencil, moves on steel friction rollers, concealed in the capitals of the brass supporting pillars. In connexion with it is an astronomical clock, which vibrates seconds, and needs winding once in 16 days only, so that somewhat more than a chart of tidal curves, extending from new moon to full moon, or *vice versa*, can be registered without any attention being required.

The instrument is also furnished with a system of wheels by means of which the depth of water is shown on a circular dial; that placed at the mouth of the Tyne

is illuminated at night, and can be seen at a great distance at all times.

The instrument is elegant in appearance, and seems to be perfect in its action, and is the only one which shows time and tide by separate dials. A Prize Medal was awarded to Mr. Hewitson.

NEWMAN (No. 674, p. 468\*) has exhibited a self-registering tide-gauge. This instrument consists of a metal cylinder 30 inches in length and 8 inches in diameter, moved by a clock, and performing one revolution in 24 hours. A pencil moved by a float is suspended by an endless chain, and maintains always the same buoyancy. The pencil attached to the chain is carried over two cylinders, one of which contains a spiral spring, and is so contrived, that the marking of the change of tide is immediate. On the face of the clock is shown the height of the tide at the time of observation. It also registers the highest and lowest for the day. The papers require replacing every fortnight, and the pencils used are metallic.

The chain consists of a given number of links, the ends of which are not soldered together, which in its progress loops over the spikes in the barrel; this method will do well for a time; but as the links cannot keep all of the same length, it is probable that some will not catch, but slip past, and cause error in the register.

#### Acoustics.

HEARS (No. 615, p. 476) exhibits a pulpit, to the reading-desk of which is attached a receptacle for collecting sound, to which a gutta-percha tubing is connected, intended to be carried under the floor, or otherwise, to the pew of the deaf person; the terminal of the tube, which is intended to be applied to the ear, is of ivory.

REIN (No. 629, p. 477) has exhibited several instruments for acoustic purposes; one of these may be worn without being seen, is adapted to the shape of the ear, and requires no spring. The power is great in proportion to its small size, the entire length of tube being 8 inches.

Another acoustic contrivance, which may be worn as a lady's head-dress, without being seen.

Also a new promoter of hearing. The great fault in instruments of this class has hitherto been the concentration of the sound in one ear only; so that, whilst the sound was much increased in loudness, it remained, if possible, still more confused and indistinct. To obviate this inconvenience, Mr. Rein designed this contrivance, which is to be worn on the head, and is adapted to both ears: by means of it the faulty ear is called into equal action with the healthy one. When worn by ladies, it may be quite concealed by the hair.

An acoustic chair. This is so constructed that its power by reflection is doubled to either ear, and may be used at pleasure for one or both ears. In the latter case the power is fourfold. The chair is rendered acoustic by the arms being made hollow, and terminated by a design suitable to the free admission of sound, which is conducted to the ears of its occupant, by two small tubes, projecting from the inner side of the back of the chair.

An acoustic vase, designed by its construction to collect the sound from all parts of the room. The vase being placed on a small table, the attachment of the tube is skilfully concealed beneath the table through which it is inserted; contrary to other contrivances for the same purpose, it is not trumpet-shaped, and in its appearance does not resemble an acoustic instrument.

All acoustic instruments hitherto made, partake in one or less of the trumpet form; and all agree in one respect, viz., that the mouth or orifice for the reception of sound, is bounded by a line, generally circular, every point of which is in one plane; and, therefore, it is necessary that the voice of the speaker should be directed as nearly as possible at right angles to this plane. Some instruments have been made consisting of a large metallic receptacle for the sound, with a long flexible tube attached to them; but they are very unsightly objects. The vase above described differs from these in the following particulars:—

1st. That the orifice for the collection of sounds is arranged on a circular plan, so that when the instrument is placed on a table in the centre of a room, the deaf per-

son can hear speakers in any direction, with distinctness proportionate to his degree of deafness, or the tone of voice used by the speaker.

2nd. That it has not the appearance of being an acoustic instrument.

3rd. That it may be used as a flower vase. It is of course furnished with a flexible tube for the purpose of conveying the sound from the vase to the ear.

Mr. Rein has exhibited more than one design of the acoustic vase, several acoustic bells, also an acoustic walking-stick, which may be applied to either ear, without being recognized as an acoustic instrument.

Several portable telescopes, adapted to various degrees of deafness.

An acoustic instrument, or "Social Companion," to enable any number of persons to converse with one who is deaf, and requiring no change of place.

A conical and flexible whispering tube, so constructed that extremely deaf persons can distinctly hear and hold conversation even when spoken to in a low tone of voice.

A whispering gube, and ear-caps or reflectors, which last may be worn without a spring.

WATKINS and HILL (No. 659, p. 466\*) exhibit a syrene; an instrument used in acoustics for demonstrating the production of a musical sound by a succession of musical impulses. The invention of M. Cagniard De La Tour.

#### Planimeters.

SANG (No. 338, p. 448) has exhibited a planimeter. The peculiarity of the construction consists in the product of the ordinating lines being given by the motion of a disc over the surface of a cone, instead of over a plane, by which means, the motions representing both the ordinates may be taken directly from the motion of the tracing point. In the Tuscan instrument the motion which represents one of the ordinates is conveyed through a rack and pinion, and in those of Swiss and German construction, through a hand and pulley. The arrangement of Mr. Sang is designed to obviate the shake necessarily caused by the teeth of the rack, and by the elasticity of the band of the pulley.

The parallelism of the instrument is trusted entirely to the simple rolling of two heavy wheels over the paper. This is rendered more certain in the foreign instruments by the rollers working in guides as on a railway. All, however, appear free from any tendency to divergence in this respect.

Mr. Sang's instrument possesses a practical advantage in the readiness with which it may be placed at once on a drawing of any size.

The error contained in the results given by instruments of this class generally arises from the shaking or elasticity of the parts which connect the index with the tracer. This error in practice may be easily corrected by measuring the figure twice; at one time placing it so that the shortest breadth is represented by one of the motions, and at another, so that the longest breadth is represented by the same motion. The average of the two results will be very nearly the truth. The Jury considered Mr. Sang as well deserving Honourable Mention.

GONELLA (Tuscany, No. 70, p. 1298) has exhibited a planimeter. All, or very nearly all, the planimeters, of which the Exhibition contains several, turn upon the mechanical integration of the differential expression for the area of a curve traced on a plane surface, and are most readily conceived on that old and now almost forgotten view of the differential calculus, which regarded the differential of a magnitude as a measure of the velocity of its increase at any instant. Suppose a straight line to be carried with a uniform motion along the base line (or abscissa as it is termed), of any curvilinear area, remaining always parallel to itself and perpendicular to the base line; and that, during this motion, a moveable point in the line so carried is kept always on the circumference or boundary line of the area. Then it is clear that the velocity of increase of the area will be proportional to and therefore measured by the length of the ordinate, or point of the moveable line included between the base line and describing point.

Suppose, again, that a circular disc or wheel can be made to revolve with an angular velocity, always proportionate to the same ordinate. Then will the total angle of revolution described by it from zero increase by similar increments with the curvilinear area, and consequently be always proportionate to and a measure of that area. The area, therefore, may be in effect *read off* upon its circumference by any method which shall keep account of the number of revolutions and parts of a revolution made by this wheel, which may be called the *integrating wheel, disc, or roller*.\*

If a circular disc be made to roll (whether by rack-work or friction) upon a line parallel to that on which its centre moves uniformly, its angular motion will be uniform. Supposing then a racket bar, parallel to the abscissa, and incapable of motion in the direction of its length, to work into a toothed wheel on the axis of such a disc, that disc will (however carried) revolve uniformly when the motion of its centre parallel to its abscissa is uniform. To convert this uniform angular motion into one proportional to the varying ordinate is, therefore, the problem of planimeters so conceived.

If the circumference of two circles, whether in the same or in different planes, be so connected, either by teeth, as in ordinary wheel-work, or by mutual friction and adhesion, their angular velocities are inversely as their radii; so that if the radius of one of them be constant, its angular velocity will be directly as the radius of the other. Any disposition of the parts of a mechanism then, which shall secure the condition, that a roller or rolling disc shall be carried round on its centre by contact with a uniformly revolving circle of a radius, always equal to the length of the variable ordinate, contains the solution of the problem. The uniformly revolving disc may be horizontal (that is parallel to the surface of the area to be measured), and the integrating roller at right angles to its plane, having its axis horizontal and parallel to the ordinate as directed to the centre of the disc. This is the construction adopted by Gonella and Gaspard Wettli, or it may be perpendicular to the horizon, being no other than the transverse section of a cone whose vertex lies in the abscissa of the curve, and the radius of which section is therefore proportional to the distance from the vertex, or to the ordinate. This is the construction adopted by Sang (No. 338); but it is only justice to Mr. Gonella to state that this construction is expressly indicated and figured in his original Memoir on the Planimeter, which carries the date 11th June, 1827, in which there will be found a full account of Mr. Gonella's instrument, and a very elaborate (though unnecessarily complicated) exposition of its theory, and to which we therefore refer for the particulars.\*

A very great saving in the expenses of computation in the reduction of local surveys, to give the areas of districts, parishes, estates, and fields, as laid down in maps, has been found to result from the use of these instruments, where indications are sufficient for all practical uses.† A Council Medal was awarded to Mr. Gonella.

LAUR (France, No. 567) has exhibited a planimeter, in which the area of a plane, supposed to consist of triangles, is first reduced, by geographical construction, to any right-angled triangle. On a rectangle of either gelatine paper or transparent horn are engraved a series of hyperbolas, such that the product of the ordinate and abscissa contained for each, shall change from hyperbola to hyperbola by a constant increment. The extremity of one side of the triangle then being made to coincide with the common centre of all the hyperbolas, and that side with the asymptote, the opposite angle will of necessity fall on one or between two adjacent ones of the hyperbolas, and

its area (or its double) will be therefore expressed by the ordinal number of the hyperbola, or the number of the lowest *plus* or proportional part for the distance between that and the angle, as compared with the interval between the two consecutive curves.

This instrument, termed an "alarithme," is intended for the use of persons engaged in geodetical operations, and it offers a simple and ready means of measuring the surface of any portion of a plane. The Jury awarded Honourable Mention.

WETTLI (Switzerland, No. 84, p. 1072.) exhibits a (Goldschmidt's) planimeter, for measuring the area of any plane figure, by the simple operation of drawing a tracing point round its periphery, the area being indicated by the divisions of a circle, which is fixed.

The disc is of glass, covered with paper, and receives the movement of rotation by suitable and simple mechanism. The results obtained by this instrument have been found to be correct within 1-1000th part of the area. The Jury awarded a Prize Medal.

AUSFELD (Gotha, Prussia, No. 704, p. 1089) exhibits a planimeter, consisting chiefly of a small roller, moving upon a horizontal disc. The instrument is well conceived, and tolerably well carried out. The Jury awarded Honourable Mention.

#### *Dynamometers.*

TAURINES (France, No. 386, p. 1196,) has exhibited a dynamometer, adapted for the measurement of very great powers. The driving power, instead of acting at right angles to the spring to be bent, acts lengthways, or rather in the direction of the extreme tangent of a circular arc of nearly 120°, into which the spring is formed, one end being pressed on by the driving power, the other inserted at right angles into a strong radial bar emanating from the axle to be driven. Two such springs nearly complete the circle, and by compression are rendered more convex, and their opposite points made to recede. These opposite points are connected two and two by two other oblique-acting springs, which magnify the motion communicated to their extremities, and through the medium of a third pair, connecting their opposite points, ultimately push along the axle. A cylinder of brass serves as an index, and reads off a scale indicative intrinsically of the distance to which the cylinder is carried out from its zero point, but of which the graduation is so executed as to indicate the power necessary to drive it to that distance: this graduation is executed by trial. The instrument is useful only for heavy engine work. A Council Medal was awarded to Mr. Taurines.

CLAIR (France, No. 1151, p. 1233) has exhibited a dynamometer in which the driving-wheel of any axle, when thrown into gear with the moving power, is brought not at once to lock into connexion with the axle, but to press at once on a strong straight steel spring standing at right angles to the axis. The degree of flexure of this spring is read off by an index, to the measure of the force required to overcome the resistance, and drive the axle round. It is, therefore, applicable only to moderate powers, such as may be measured by a spring of reasonable strength, bent by direct action. It can be used either horizontally or vertically. By the application of a train of wheel-work, the movement is made self-registering in every instance, and the work done with the variations from instant to instant of the driving power required to overcome the resistance, is registered.

M. Clair has also exhibited the model of a locomotive fire-engine; a vertical section is also exhibited upon a large scale.

DE BURG (Austria, No. 130, p. 1014) has exhibited a dynamograph. This is an instrument not unlike Regnier's, with the addition of a piece of clock-work, regulated by a fan, which can be set in motion or stopped at pleasure; it carries a pencil along the index of the instrument, recording at any moment the position of the index on a piece of paper stretched beneath it. Honourable Mention is awarded to this exhibitor.

CAZAUX (Netherlands, No. 89, p. 1147) exhibits a dynamometer, intended for use as a dynamometer for ploughs, but applicable to the measurement of other strains, and

\* Opuscoli Matematici. &c. &c. Di Tito Gonnella, Professore di Matematiche Nell' I. E. R. Accademia Delle Belle Arti di Firenze. Firenze, 1841.

† Tracing with a pen dipped in dilute sulphuric acid on paper of a moderate and uniform thickness by the aid of transmitted light, and weighing the portion cut out by the corrosive action of the acid on exposure to heat, will enable any one to extemporise a planimeter, following the most intricate details of a machine, and giving the total area with a very considerable approximation.—J. F. W. H.

furnished with a chronometric controller. It consists of two levers fixed to an iron frame, which mutually act on each other by a joint; to one of these the plough is attached, and to the other a counterpoise which constitutes one of the factors for the measurement of power, as it changes its position with a change of strain, which changes are marked as the lever moves.

The chronometric controller consists of two watches provided with seconds-hands, one of which is unaffected by the pull, and merely indicates ordinary time, whilst the other is acted upon by the varying position of the lever, in such a manner that its rate per minute varies with the varying strain, and is self-registered. By this means all varying resistance is recorded, such as is experienced in the towing of a ship, &c., cases in which the ordinary dynamometer acted upon by means of a spring, is found to fail.

#### *Crystallography.*

LEESON (Class I., No. 8, pp. 120, 121.) exhibits a very beautiful collection of crystals; the apparatus for illustrating the crystallographic speculations published by Dr. Leeson, in the third volume of the Memoirs of the Chemical Society; a double-refracting goniometer; and numerous models of crystals. A Prize Medal was awarded to Mr. Leeson.

It is difficult to understand why the remark "rectangular" is annexed to a model labelled antimony. For according to the independent observations of Marx, G. Rose, M. Zippe, and Haidinger, antimony crystallizes from fusion in a form, the faces of which make, with each other, angles differing nearly two and a half degrees from a right angle.

MITCHELL (Class I., No. 9, p. 121) exhibits a collection of crystals: some very beautiful card-board models of crystals, in which the faces of each have a distinctive colour, as in some of the plates of Temant's Mineralogy, and are marked with symbols according to the notation adopted by different crystallographers.

Also some very ingeniously contrived skeleton models, showing the outline of all the simple forms of a crystal-line species, referred to the same axis.

Other models, some to illustrate theoretical views, are exhibited by Mr. Mitchell, according to which, the simple forms of crystals of any system may be derived from those of a crystal of the cubic or octahedral system. A Prize Medal was awarded to Mr. Mitchell.

LOHMÉ (Prussia, No. 83, p. 1053) exhibits an extremely good collection of models of crystals, selected by G. Rose.

SCHNÖDER (Grand Duchy of Hesse, No. 77, p. 1129.) exhibits models of crystals, described in Kopp's "Einleitung in die Krystallographie," on a large scale, which are probably the best-executed models that have yet been made: he also exhibits various models of geometric solids, which appear to be as well executed as the crystals. A Prize Medal was awarded by the Jury to Professor Schröder.

BATKA (Austria, No. 135, p. 1014) exhibits some very good models of crystals in glass.

BERTAUN (France, No. 1549, p. 1251.) exhibits models of crystals.

#### *Drawing Instruments.*

VARLEY and SON (No. 257, p. 436) have exhibited a graphic telescope and table; also a small graphic stand, adapted for use on an ordinary table.

The telescope is furnished with a variety of powers, and affords every variation of size in the object to be traced, which may be sketched to the true perspective distance of the picture on which it is to be placed.

The field of view is large, but the picture may be extended by moving the telescope, and shifting the paper, there being a means of applying correction, if necessary.

The paper or drawing surface may be placed in any convenient direction, and inclined at any angle, the instrument affording facilities for delineating objects in all positions, whether overhead, on the floor, or right and left. The image can be adjusted with equal precision at what distance soever the eye may be removed from the paper, and may also be reversed, for lithographic purposes.

This instrument has assisted in the production of the great "Panorama of London, as seen from the top of St. Paul's," at the Colosseum, in the Regent's Park, and in that of Corfu, the coloured sketches for which, on a large scale, were made by the late Joseph Cartwright, Esq.

The graphic telescope is designed to afford assist to artists, architects, and draftsmen, by presenting to the eye a correct image of the object to be traced, in any direction and of any size required.

In order to trace telescopic images, great steadiness and portability are required. Both these requisites appear to be combined in the graphic table exhibited by Mrs. Varley. The framework is so constructed as to be extremely light and steady; the joinings are made with hinges, from which the pins may be removed, and the instrument packed into a small compass. The table itself is supported upon a braced tripod, and admits of adjustment upon any surface, however irregular; it can also be supported at any angle.

ELLIOTT and SONS (No. 320, pp. 443, 444) exhibit a fine magazine case of drawing instruments, inclusive of all the recent improvements; the two trays with which it is furnished, and the interior of the lid contain metal rulers, sectors, triangles, ivory sectors, parallel rules, pocket rules, a graduated joint for taking angles, &c. The metal sectors are well divided, as are also those made of ivory. In the drawers is a complete set of water colours. This set of instruments, the case of which is in itself a fine piece of workmanship, was rewarded with a Prize Medal.

The same exhibitors have another case of instruments, of good workmanship, and highly ornamented by engraving and chasing. They exhibit also various sets of ivory sectors, divided from 10 to 100 to the inch, and ivory parallel sectors, capable of being used on both sides, with divided edges both sides. They also exhibit a small instrument called an opisometer, intended for measuring the length of curve lines. It consists of a small roller, which, having been passed over the lines, is made to perform the same number of revolutions over a scale.

PILLISCHER (No. 269, p. 437) has exhibited an elliptograph. The principle upon which this elegant little instrument is made to describe an ellipse, is that of a point revolving in a circle about a centre, with an angular velocity the double of that with which the centre revolves about a fixed centre. The cogs on a moveable bar, and wheels of the instrument are so arranged that the short arm which holds the style performs 100 revolutions while the long arm performs one. By varying the relative lengths of the two arms an ellipse of any form may be drawn. The semi-major axis of the ellipse will be manifestly equal to the sum of the two radii or arms, and the minor axis equal to their difference. A Prize Medal was awarded to Mr. Pillischer.

SIMMS (No. 741, p. 475\*) exhibits an isometrical elliptograph. Invented by G. B. Airy, Esq., the Astronomer Royal.

DOBSON (No. 323, p. 446) has exhibited many well-made sets of drawing instruments, so far as could be seen through the glass case, which was never opened for the examination of the Jury.

TREE and Co. (No. 324, p. 446) have exhibited some well-made drawing instruments, with many accurately divided scales for different purposes. The Jury awarded Honourable Mention.

PARKE and SONS (No. 337, p. 448) have exhibited well-made drawing instruments, and several well-divided scales.

DIXEY (No. 271, p. 438) has exhibited several mathematical instruments, amongst which is a divided ivory rolling parallel rule.

HAGGARD (No. 328, p. 446) exhibits a double protractor, intended for measuring angles, and determining heights and distances.

GRAHAM (No. 355, p. 449) exhibits an ivory rule, one foot in length, and an inch and a half in breadth, for the purpose of exhibiting by inspection the circumference of a circle when the diameter is given, and *vice versa*, and for showing the side of the square equal in area to that of a circle, whose diameter or circumference is given.

One side of the rule contains three lines extending its

whole length, the upper side of each being divided into 100 parts. The under side of one is divided into 315 parts, 314 of which are equal, the remaining part being equal to 0.16, and the relation existing between the divisions above and below, the lines being that of the diameter to the circumference of the circle.

The under side of the second line is divided into 89 parts, 88 of which are equal, the remaining one equal to 0.623. On the diameter of a circle being given, on the upper side, the side of the square whose area is equal to that of the circle of that diameter, is read at the same point on the under side.

The under side of the third line is divided into 283 parts, of which 282 are equal, and the other is equal to 0.095. The relation existing between these lines at the same point, is that of the circumference of a circle on the upper side, to the side of the square (to one place of decimals) equal in area to the area of the circle.

The reverse side of the scale is occupied by scales of equal parts.

It is understood that Mr. Graham has arranged other lines, showing the relation existing between the area of the circle when the diameter is given; and another giving the area when the circumference is given.

MATTHIAS (No. 393, p. 451) exhibits an instrument for dividing a given line quickly into any number of equal parts, less than 100, by a method susceptible of more extended use. The principle of the instrument is that of an angle and parallel lines, the angle being formed by the two legs of the instrument, which may be opened to the distance of 20 inches, any space less than which can be divided; it is made of ivory.

HONNE, THORNTON, and WOOD (No. 220, pp. 434, 435,) exhibit T'ebay's universal planing-rule, the novelty consisting in the arrangement of the division of the odd and even scales; by continuing the graduation to the edges, the necessity of making use of dividing compasses is obviated.

GAVARD (France, No. 235, p. 1197) exhibits improved pentagraphs; the improvements, which consist principally in a better arrangement of the steadying weight of the pivot, and the larger size of the wheels, add greatly to the smooth working of the instrument, so much so that even persons unaccustomed to its use may produce smooth and unbroken lines. In the hands of Madame Gavard it performed several beautiful tracings of great delicacy and difficulty, among which we may specially mention a map of France, showing with great distinctness the departments, comprised within two inches square. The steadiness of the instrument when in use is very greatly increased by the improvements of M. Gavard.

Gavard also exhibits a beam compass of most finished workmanship, and an instrument for drawing from nature by mechanical means. A telescope with a cross wire in its focus is suspended in a jibbal frame, near the eye, and so as to keep the position of the eye nearly fixed. It is so balanced and so lightly hung as to allow the most perfect freedom of motion, and the cross of the wires being carried along every part of the outline of the object.

The object end of the telescope is suspended over a pulley on a vertical support, by a silk line, which is conducted to the base of one support, and thence along a horizontal bar, to a pencil-holder sliding on the bar. Thus any movement in the vertical direction is traced on paper. To trace the horizontal movements in like manner, the upright support and the horizontal bar are made moveable on rollers to the right and left. The instrument is of most delicate execution, and works with perfect smoothness. As specimens of its performance are exhibited a tracing of a ceiling of the Luxembourg, of singular complexity; and a series of outlines, in illustration of the interior of the Palace of Versailles, with its rich and elaborate decorations, which are executed with exquisite fidelity and delicacy.

By adapting a microscope instead of a telescope to the jibbal frame, the outlines of a microscopic object, as of an insect, wood section, &c., can, in like manner, be traced with perfect fidelity, and on any scale. Honourable Mention was awarded to M. Gavard.

LÜTTIG (Prussia, No. 81, p. 1053) exhibits several cases of well-made drawing instruments, some in German silver and some in brass. The Jury awarded Honourable Mention to M. Lüttig.

REIFLER (Bavaria, No. 34, p. 1100) exhibits a case of drawing instruments; and Honourable Mention was awarded by the Jury for his new method of fixing the two parts of a compass together by means of plane surfaces with steadying pins and screws.

HOMMEL-ESSER (Switzerland, No. 81, p. 1272) has exhibited drawing instruments, distinguished for the care with which the most minute details have been finished. A Prize Medal was awarded to this exhibitor.

GYSI (Switzerland, No. 85, p. 1272) has exhibited drawing instruments. The remarks applicable to the preceding exhibitor, apply equally to these, and it may be observed, that the steel used by both exhibitors is of the finest quality and extremely well tempered. A Prize Medal was awarded to this exhibitor.

KERN (Switzerland, Nos. 88 and 92, p. 1272) exhibits some well-made drawing instruments, which, in common with those of the Swiss exhibitors, are made in different parts, which can be readily separated and cleaned with ease. The Jury considered Mr. Kern as deserving Honourable Mention.

IMPERIAL LJOSSK WORKS (Russia, No. 169, p. 1372) exhibit a full set of twenty-seven drawing instruments, comprising eleven different articles 5 inches in length; a set comprising ten pieces of 3 inches in length, and mounted in silver.

The following drawing instruments are exhibited mounted in brass: a full set of twenty-four pieces; a set of eleven pieces 5 inches in length; and a set of ten pieces 3 inches in length.

The following pocket instruments are exhibited:—Folding or silver-mounted compasses; brass compasses in silver sheath; and several other compasses mounted in brass, some furnished with pencil tubes, and mostly folding up. All these instruments are well made, and include the recent improvements; they deserve very Honourable Mention.

VIBERG (Sweden, No. 14, p. 1350) exhibits two small cases of drawing instruments, containing each a protracting semi-circle, a pair of large steel pointed compasses, two smaller for steel pens on exchangeable pencil points, and a steel ruling pen. They are very neatly made.

LITTMAN (Norway, No. 15, p. 1350) is stated in the Catalogue to have exhibited drawing instruments, but careful search being made for them, they were not found among the objects in this compartment of the Exhibition. (See Microscopes, levels).

NITZSCHMANN and VACCANI (Prussia, No. 706, p. 1089) exhibit many sets of drawing instruments, of an exceedingly low price. The Jury awards Honourable Mention for cheapness.

ROCHETTI (Austria, No. 136, p. 1014) exhibits a case of drawing instruments of sixteen pieces, compasses, &c., of brass and steel, of very elegant construction. There is no protractor, ruler, or scale.

PENROSE (No. 318, p. 443) has exhibited registered screw and sliding helicographs for drawing volutes, scroll work, and spirals of various kinds. The outline may be drawn on paper by means of an impression obtained from the disc by transfer paper, either with ink or pencil by the sliding helicograph. For a description of these delicate and well-constructed instruments see the Illustrated Catalogue.

A Prize Medal was awarded to Mr. Penrose.

#### *Orreries, Planetariums, and Astronomical Machines.*

It is a matter of regret that the time and ingenuity which have been devoted to the several machines of this class in the Exhibition, have not been better directed. Those exhibited do not indicate any improvement over the many which have been constructed, one only, perhaps, excepted, viz., a vertical orrery of large dimensions, made by a working man, after his own design, and it is understood, without ever having seen an orrery of any kind.

The time, ingenuity, and expense, devoted to machines

of this kind, are wasted; they are of no use to the student of astronomy, and the erroneous impressions which they give are always dispelling to the eye of the astronomer.

If they be of any use in the lecture-room to children and novices, certainly Facy's vertical orrery is the best adapted for this purpose.

#### Orreries.

FACY (No. 195, p. 431) has exhibited a vertical orrery, showing the relative periodic times of the planets. A comet's orbit is also introduced which extends from within that of Mercury to some distance beyond Neptune. The Jury voted a Prize Medal to Mr. Facy for the ingenuity displayed by him in the construction of this orrery.

NEWTON and SON (No. 212, p. 434). An orrery, showing the motions of the earth and moon, the planets and their satellites. The mechanism by which these several movements are performed is actuated by clock-work. They exhibit a smaller orrery, constructed on the same principle, but showing only the motion of the earth and moon.

PLANT (No. 215, p. 434) has exhibited an orrery, the sun being represented by a luminous body; the seasons, phases of the moon, and other natural occurrences are clearly shown. It may be used to the greatest advantage in a darkened room, when the sun of the orrery will best show the various changes attendant upon the different motions of the several bodies.

#### Planetariums.

NEWTON and SON (No. 212, p. 431). A planetarium for educational purposes, intended to show the diurnal and annual motion of the earth and moon, also the respective position of their satellites. It is exhibited for cheapness.

LE FEVRE (Jersey and Guernsey, No. 10, p. 941) has exhibited an orrery; it is designed to show the motion of the moon around the earth, her daily variation and position at the time of new and full moon, also to exhibit the cause of eclipses, either partial or total. It is intended for the use of schools.

MASSETT (Switzerland, No. 95, pp. 1272, 1273) exhibits a planetarium of an extremely simple construction, in which the motions of the sun, the earth, and the moon are shown. It is remarkable for its cheapness, and Honorable Mention was voted by the Jury.

MOLLISON (No. 585, p. 475) has exhibited a pedestal planisphere. The places of the stars being perforated, when the instrument is held up against a light background, they appear as luminous points. It is 20 inches in diameter, and designed for educational purposes.

BRACK (No. 354, p. 449) has exhibited the model of an instrument called a Periphon, designed for the simple elucidation of solar and lunar phenomena. It is furnished with a terrestrial globe in the centre, and is intended to describe the apparent diurnal motions of the sun and moon, also the daily increase and decrease of the sun's declination, and to determine the time of sunrise, at any place on the globe; the causes of the harvest moon, &c. The model is in diameter 6 inches, which is about a third of the proposed size. It consists of a fixed meridian circle graduated on both sides; on one similarly to the brass meridian of the common globe, and on the other to show altitudes; a horizontal circle, showing the zodiac signs, &c.; a terrestrial globe, placed in the centre of the sphere, which turns freely on an axis; two small peaglobes, to represent the places of the sun and moon, and which slide on circular wires; these wires themselves turn freely in their bearings. This instrument shows readily the time of the sun rising and setting at any place exterior to the frigid zones, and various other phenomena of an analogous nature.

MATTHEWS (No. 193, p. 431) has exhibited an Astorrama. This is a concave representation of the heavens upon a small umbrella, which opens and closes at pleasure. The material with which it is covered is perforated to show the places of the larger stars.

MALLOCH (No. 208, p. 443) has exhibited a mechanical indicator for teaching geography. This is a contrivance for rendering purely mechanical the acquirements of the first rudiments of geography. A map is mounted upon a

light framework, a few inches in depth, to permit the studs to work freely. These studs themselves represent cities, towns, &c., on the map, beneath which is placed an index giving the name of each place thus represented. On the same line with the printed name is placed a moveable stud. By keeping down one of the studs on the surface of the map, a corresponding one in the index instantly rises, the printed name beside it giving the required information.

This is an invention of Mr. Malloch. The model which he has exhibited is, he considers, capable of still further improvement. Mr. Malloch also has exhibited a mechanical indicator of eclipses.

MURDOCH (No. 202, p. 431) has exhibited an eclipse indicator. This is a circular table embodying by the motion of a circle of months on a cyclo-circle, with intervals of 18 years 11 days, the actual results of a previous calculation of the moments of conjunction, both for lunar and solar eclipses from 1647 to 2001. The rules given for setting and reading off the circles being adhered to, the precise moment of the ecliptic conjunction and other particulars are obtained.

RYLES (No. 190, p. 431) has exhibited an apparatus for showing the ebb and flow of the tide.

NEWTON and SON (No. 212, p. 434). An armillary sphere, mounted on a brass meridian and attached to a brass stand.

ZIDERMAYER (Austria, No. 132, p. 1014). A chronoglobium and planetarium, a flat board on which are framed the orbits of Mercury and Venus. The earth and moon are attached to a small rolling carriage, as described in M. Guénal's instrument, by which the rotation of the earth and the phases of the moon are represented. Mars is also made to revolve on his axis by a similar contrivance, viz., by establishing a rolling drag on the orbit.

DISK (Austria) exhibits a globe of the earth, about five inches in diameter, within a glass sphere, on which are placed the fixed stars. The positions of the sun and moon are marked at any given moment by a simple mechanism.

RICHARDS (No. 188, p. 431) exhibits a "geographical instructor," a piece of mechanism in which the sun (represented by a gilt ball elevated on a wire) is presented vertically, to every point of the earth between the tropics, by a compound movement of rotation on a horizontal axis, the revolving ball being pulled and pushed along it, by a movement to and fro corresponding in extent to the time of the sun's declination at the moment. The law of this movement is given by a train of clock-work, of which one peculiarity is the prolongation of the axis of the globe into a very long pinion, so as to allow the teeth of the driving-wheel to act upon it, however far displaced from a mean position. Another, that of the communication of the rotary motion from the *primum mobile* by a hook-jointed axis; the to-and-fro motion of the pinion prolongation of the axis not allowing the clock-work to be centrically placed in some point in that direction.

DETACHE and HOUVIN (France, No. 1589, p. 1253) exhibit a uranographic apparatus (erroneously described in the Catalogue as a monographie apparatus); it consists of a table about six feet in diameter, in the centre of which is a lamp representing the sun. The earth with the moon attached is carried round on an arm, by a piece of clock-work, the *primum mobile* of which is not a spring, or any internal power, but the roller on which the mechanism rests, and which revolves as the earth is carried round on the table. This, by a train of wheel-work, communicates to the earth its diurnal motion, preserves the parallelism of its axis, and gives to the moon all the movements imitative of real ones. This mechanism is the invention of M. Guénal.

#### Dialling.

NEWTON and SON (No. 212, p. 434) exhibit a spherical sun-dial. The hour is indicated by means of the shadow of the pole or axis of the sphere being made to fall within side of the zodiacal belt, on the outside of which the signs of the zodiac are depicted. This is well adapted for a lawn.

The articles exhibited by Mr. Newton are distinguished by cheapness and good finish generally.

LAWRENCE (No. 115, p. 418) exhibits a sun-dial applicable to all north latitudes.

ELLIOTT and SONS (No. 320, pp. 443, 444) exhibit a spherical sun-dial.

DARNELL (No. 383, p. 451) exhibits an universal sun-dial.

COX (No. 347, p. 443) has exhibited a portable instrument for ascertaining correct time by equal altitudes of the sun.

UHLMAN (Netherlands, No. 85, p. 1147) exhibits an equatorial sun-dial made of copper, furnished with a moveable hour, minute-hand, &c., which, by suitable mechanism and a lens, may be made to discharge a piece of ordnance at any time required.

### Globes.

JOHNSTON, A. K. (No. 198, p. 431), has exhibited a terrestrial globe, 30 inches in diameter; it shows the geological structure of the earth, indicates the currents of the air, trade winds, monsoons, &c.; also the currents of the ocean, trade routes, and isothermal lines, or lines of equal temperature. The stand, which was executed by N. Davidson, of Edinburgh, is carved in walnut, and is of elaborate and elegant design. A Prize Medal was awarded by the Jury for this globe.

NEWTON and SON (No. 212, p. 434) have exhibited a large manuscript celestial globe, 6 feet in diameter. The positions of the stars have been laid down from their positions as calculated for the year 1860.

Several pairs of globes, ranging in size from 12 inches to 25 in diameter, variously mounted in different materials.

A glass case, containing several small-sized globes, varying from 1 inch to 9 inches in diameter. These are all differently mounted.

A pair of 12-inch globes are exhibited for economy of construction and improvement in the manner of mounting; the pole or axis of each globe remains stationary, whilst the horizon is moveable.

Slate globes are exhibited of various sizes, having the meridians and parallels of latitude marked upon them. The material of which they are formed affords the student means of filling in the outline map with common slate pencil. This is advantageous as applied to educational purposes. The globes exhibited by Messrs. Newton are distinguished by good finish generally, and by cheapness. A Prize Medal was awarded to them by the Jury.

FLETCHER (No. 200, p. 431) has exhibited a pair of terrestrial globes, and one case showing the various stages of globe-making. The contents of the case are as follows:—

1st. An iron mould: by the adoption of iron instead of wood, the material generally used, all danger of warping is avoided, and much time is consequently saved.

2nd. The axis of the globe.

3rd. The globe in its rough pasteboard form.

4th. A globe coated with composition, resting in an iron semicircle, the revolving in which gives its perfectly spherical form.

5th. The engraved copper plate.

6th. The impression from the copper plates.

7th. The globe pasted and partly coloured.

The globes are well made and finished, and the process of globe-making, as exhibited by Mr. Fletcher, is interesting.

READHOUSE (No. 677, pp. 468\*, 469\*) has exhibited a model of the moon in high relief, the craters, mountains, &c., being modelled from actual observation with a 1-foot reflector, power about 55, and the occasional use of a reflector power, 90 (the use of the latter being procured only at the expense of a journey of 35 miles). It merits commendation, though the scale of height has been pitched too high; and the effect is injured rather than improved by silvering or gilding portions of the surface, the whole being composed of a dark material.

ARMON (No. 218, p. 434) has exhibited a globe 25 inches in diameter, with the celestial and terrestrial maps superimposed one upon the other; also a globe of papier-mâché,

divided into forty-eight pieces, to be taken to pieces and rebuilt at pleasure; and a skeleton globe, to show how to rebuild the globe in its frame. The power of taking the globe to pieces is convenient for package and removal, as well as for the convenient study of any part of it. They are well made.

STOKER (No. 204, p. 433) has exhibited an angular terrestrial globe, intended for the solution of geographical problems. It is adapted for use as a common terrestrial globe, by unscrewing the cog-wheel attached to the spindle at the south pole, and substituting the horizon and meridian, the former being screwed in the upright of the stand, the latter being placed upon the globe, the angular motion given to which is designed for the better explanation of the changes of the seasons.

Mr. Stoker also exhibits a spherical geographical clock, to show the difference of time between two given places whose longitudes are known, and is intended to be of more general use than those ordinarily constructed.

BENTLEY (No. 213, p. 434) has exhibited a plain globe. The northern and southern hemispheres are printed on circular pieces of card-board, each hemisphere moving under a brass meridian, which confines it to its place, and affords the same facility as an ordinary globe for working problems.

PAXON (No. 191, p. 431) has exhibited a lunarian, with a contrivance for showing the phases of the moon.

MARRATT (No. 409, p. 454) exhibits a Russell's globe of the moon, mounted as originally sold, with movement in brass for exhibiting the librations, &c., in longitude and latitude.

GOOD (No. 146, p. 428) exhibits a new method of illustrating the effect of the earth's diurnal motion upon the plane of a pendulum's oscillation. It consists of one end of a radius arm, fixed in the centre of a globe; the other end being adjustable in a vertical plane, and therefore to any latitude, is made to revolve so that its time of revolution varies as the sine of latitude; the time of the revolution of the globe being its measure.

EDKINS and SON (No. 207, p. 433) have exhibited a pair of 18-inch globes. They are well finished.

GILBERT (No. 234, p. 435) has exhibited a portable celestial and terrestrial globe, made of tissue paper and inflated with air. The celestial globe is adapted chiefly for the use of the lecture-room, and may be made of any convenient size. The terrestrial is 12 feet in circumference, and is inflated either by means of an air-pump or by simply raising it to and fro from the floor, by which means it may be effectually filled in a few moments. These globes may be folded into a very small compass.

KUMMER (Prussia, No. 194, p. 1058) has exhibited a terrestrial globe in relief, 4 feet in diameter. The execution is excellent; not only have the elevations been attended to with great care, but also highlands of moderate elevation, and the courses of rivers, have received the same degree of attention. A Prize Medal was voted by the Jury to M. Kummer for this globe.

GOODYEAR (United States, No. 378, p. 1461) exhibits inflated globes two feet in diameter, of India-rubber or silk, varnished with the former material. Also India-rubber maps.

GROSSELLIN (France, No. 249, p. 1188) exhibits georamas and uranoramas, to be used as lamp-shades; also some very good and distinct celestial globes, in which the figures and constellation boundaries are neatly and prettily laid down, so as not to confine the representation of the stars.

ZIEBERMAYER (Austria, No. 132, p. 1014) exhibits a small terrestrial globe, enclosed in a glass sphere, on which the celestial sphere and stars, &c., are traced. By means of mechanism the places of the sun and moon among the stars are shown.

RIKIL (Austria, No. 131, p. 1014) has exhibited a small globe of the moon, about 10 inches in diameter; the engraving is of a sepia colour, somewhat faintly tinted, and of a seleno-topographical rather than a pictorial character. Some of the principal names are inserted. It is mounted on a brass pillar, with a horizontal circle showing lunar longitudes, and a vertical one for latitudes; the lunar axis is vertical.

*Relief or Model Mapping.*

DENTON (No. 317, p. 443) exhibits specimens of model or relief mapping in its various stages, with all the tools necessary for use.

The base of the model exhibited is of slate, a material which may be procured of sufficient thickness to bear any weight in a horizontal position, may be ground sufficiently thin for framing, and may also be worked to the smoothest possible surface; thus containing the qualities necessary for the work in question, the use and accuracy of which are dependent on the material upon which the superstructure is raised.

To erect the altitudes represented in the contour map, a simple mechanical process is adopted; slips or ribbons of thin copper, cut parallel, of different breadths and of any length, are prepared. Each breadth represents a contour, and is proportioned to a certain elevation: after careful measurement with the altitudes which they are intended to represent, they are each adjusted and secured in their true position.

The model so prepared is ready for covering with plaster of Paris, a substance well suited to give a finished appearance to the work. After the plaster is dry, the whole should be scratched down until the light edge of each copper ribbon peeps to the surface. The model is thus prepared for the reception of the oil-colours intended to trace upon it the geographical details of the country.

Mr. Denton observes that it is not desirable to adopt a scale of less than 198 feet to the inch, and that the vertical scale of height should be carefully proportioned to the horizontal scale of distance. In thus exhibiting as he has done the details of a cheap, simple, and generally applicable method of surface modelling, Mr. Denton cannot fail to call increased attention to the subject.

The Jury have awarded a Prize Medal to Mr. Denton.

SCHOELL (Switzerland, No. 252, p. 1282) exhibits a model in relief of Mount Sentsis and the mountainous regions around Appenzel, including a surface of about 150 square miles. It is executed with great spirit and distinctness, and is accompanied by a chart on a smaller scale of the same region (scale 1 to 25,000), containing the data for its construction, consisting of a minutely elaborate series of contour or level lines, which covers the whole area, and is carried into every detail. The merit of the execution is enhanced by the plastic material of the model, as well as the apparatus used in its construction, being of the artist's own invention.

This work has been considered by the Jury to merit a Prize Medal.

INBURNER (No. 459, p. 450) exhibits an exceedingly well-executed relief model of the Isle of Wight, on a scale of three feet to one mile, the elevation being on the same scale. The geographical and geological features of the country are carefully delineated.

A Prize Medal was awarded to Captain Ibbetson. (Medal awarded also in Class VII.)

*Aerial Machines.*

GILBERT (No. 234, p. 435) has exhibited the model of a char-volant or carriage drawn by kites. The vehicle is in appearance similar to an open and double-bodied phaeton, with this difference, that before the driver is placed an upright spindle, surmounted by a T handle, the lower part of which is square, and carried under the head of the carriage, and fitted into a small horizontal wheel, round which is placed a band, which communicates with a similar wheel, and is fastened to the pivot of the front axle-tree. Two kites are designed to act as the propelling power; the upper one is of the ordinary form, and is called the pilot kite; the lower one is so connected with the carriage, that the driver possesses the power of varying its inclination to the wind at pleasure, an oblique direction being communicated to it by two additional lines attached, the one to the right and the other to the left hand extremity of the shoulders of the kite. By these means the plane of the kite can be inclined to the direction of the wind, and the line of traction thus rendered oblique to the direction of the aerial current, so as to enable the chariot to "haul on a wind," or steer on an

angle considerably out of the line of the wind. It has been calculated that two kites, the one 15 and other 17 feet in length, have power sufficient to draw a carriage containing four or five persons when the air is in quick motion.

This model deserves great commendation, as regards the elegance of its form and the lightness of its construction.

It is not impossible that under some circumstances the application of the propelling power of the kite may be useful, and at times attended with satisfactory results; but it would appear that as applied to nautical purposes it would be far more efficient than as a means of locomotion on land, the inconvenience attendant upon which must necessarily be great (the present arrangements not appearing likely in all their applications to carry out the sanguine hopes of their projectors); but as regards its application to vessels, it may often prove serviceable in obtaining the advantage of an upper current of air moving quickly when all beneath a certain elevation is calm; it is also likely to be of use in signalling from vessel to vessel, and might possibly serve in time of shipwreck to establish a communication with the shore; but that, with its present mode of manipulation and arrangement, it can take its place among the regularly organized systems of conveyance is without doubt fallacious. Yet it ought to be mentioned that this ingenious and singular contrivance has been so far at least reduced to actual practice by the inventor as to have been exhibited, occasionally, for a great many years, running on the road between London and Bristol; the whole distance (113 miles) having been performed on one occasion in 1846 by a party of 16 persons, in three such carriages, without accident, and with a speed occasionally as high as eighteen or twenty miles an hour. A member of the Jury recollects receiving from a friend, five and twenty years ago, the account of an excursion performed in such a carriage or carriages (as one of a party of nine persons), from Bristol.

LENTLEY (No. 237, p. 435) has exhibited the model of a rotary balloon, designed to be its own propeller by means of its peculiar shape, viz., cylindrical in the centre, and both ends formed into tapering screws. The balloon floats horizontally, and is intended to rotate by means of a band passed over its centre and worked by machinery in the car. The screw at one end is intended to draw, that at the other, to propel. By shifting the points of suspension, and thus altering the direction of the car, it is designed to guide its course through the air. This construction is intended, if possible, to overcome the direct atmospheric resistance encountered by the balloon in its progress, and to cause a more equal distribution of atmospheric pressure.

GRAHAM (No. 233, p. 435) has exhibited an aerial machine designed to take any direction required; an axle suspended over the car, and worked by a strap communication from the car, carries at either extremity a system of fan sails, with expanding joints, allowing them to assume a more or less conical arrangement. Sails of a similar kind, of the nature of oars, project from either side of the car.

SADD (No. 301, p. 442) has exhibited the model of an aerial machine. It consists of two cylindrical balloons placed horizontally, with revolving wheels, for propelling two floats, by which to raise or depress the machine at pleasure; and a rudder for the purpose of giving the required direction.

BELL (No. 715, p. 474\*) has exhibited the model of a locomotive balloon. The car, which is in the form of a boat, is constructed with a buoyant apparatus at each end, so that in the event of its descending upon the sea, the balloon and machinery may be stowed away within it. Mr. Bell has also exhibited an improved valve for a balloon. Also the model of a locomotive parachute, equipped for service.

BROWN (No. 713, p. 474\*) exhibits a balloon in which the gas expanding as the balloon rises is not suffered to escape, but is hushed for use by being conveyed into the car, which is made large and hollow to receive it as a supplemental balloon. The car is also furnished at either extremity with two centrifugal bellows pointing

obliquely outwards, by whose reaction, as the wind issues, it appears to be the inventor's design to impel and to guide the balloon.

MASON (No. 714, p. 474\*) has exhibited the model of a navigable balloon, to be worked and directed by means of sails, helm, and mariner's compass. The model exhibited is upon a scale of a quarter of an inch to a foot. From what may be regarded as its after part, project laterally axles, giving a rotary motion to sails of the nature of screw-propellers.

PLUMMER (No. 716, p. 474\*) has exhibited the working model of an aerial machine, furnished with wings or sails, put in motion by a clock-spring.

### *Calculating Machines.*

There have been very many attempts to perform numerical calculations by mechanical means, or at least such parts of them as follow simple and rigid laws. Hitherto such instruments have failed to unite correctness in the results, combined with economy of time, and, for the most part, have been limited to the performance of the first two operations of arithmetic.

To make such instruments really useful, they must have the power of executing, by themselves, the successive operations for the solution of the problem imposed on them, when the simple data for this problem have been introduced, without trial, and without guess-work.

The best machine of this kind exhibited is that of STAFFEL (Russia, 148), which, on examination, seems to combine accuracy with economy of time, and works easily and directly. The mechanism is 18 inches in length, 9 inches in breadth, and 4 inches in height, and consists of three rows of vertical cylinders; the first contains 13, the second 7, and the third 7. Upon each of the cylinders in the first row are 10 notches, corresponding with the units 1 to 10. Within each of these cylinders is a small pulley, in connection with a lever, set in motion by a slider which, when the cylinder has been turned from either 9 to 0, or 0 to 9, sets in motion the lever, and communicates its action to wheels, which carry over the figures. The pulley connected with the cylinder, the furthest from the handle, is in connection with the hammer of a bell. The purpose of this bell is to give warning to the operator, on committing an error, and constitutes a most important addition to the machine, particularly in the operation of division.

Upon each of the cylinders in the second row 10 units are placed. These seven cylinders are so fixed upon their axes, that they can bodily be moved right and left, and fixed at any part, so that the cyphers in the two cylinders can be made to correspond. This cylinder is furnished with a spike, which lays hold of and works the third row of cylinders.

The internal communication of each of the parts is brought about by means of a connecting wheel, furnished with nine moveable pegs, which are set in motion by means of an eccentric incision in the dial.

The machine is capable of performing addition, subtraction, multiplication, division, and of extracting the square root.

The operation of addition is performed as follows:—

By simply placing one line of the numbers upon the second row of cylinders (the index pointing to addition), and turning the handle, till it stops, these numbers are transferred almost instantly to the first row of cylinders, and so on successively, till all the numbers to be added are transferred, and their sum is shown on the upper row.

In performing subtraction, the first part of the operation is the same as in addition, but on placing the second line of figures on the second row of cylinders, the pointer being placed to subtraction, the handle is turned the opposite way, or against the motion of the sum, and the difference of the two numbers is shown on the upper line.

The operation of multiplication is performed by placing the multiplier and the multiplicand on the second and third rows of cylinders, and then, the index pointing to multiplication, the product will be found on the first cylinder.

The operation of division is very similar, excepting that the handle is turned as in subtraction.

These several operations were performed accurately, and with despatch.

In the performance of the square root, the following additional mechanism needs explanation. Between every division of the cylinder, in row 2, a small wheel is placed, and near it a projecting piece which acts upon a lever; when the projecting piece is near the word "rad" engraved on the cylinder, on turning the handle, the figures increase by 1. This, by other mechanism, is connected with the other two rows of cylinders. The operation of the square root is performed directly, without any guessing at numbers; but it is, comparatively, rather a long process.

Upon the whole it must be considered that Mr. Staffel has made an instrument possessed of considerable powers, and that great praise is due to him. The double motion of the handle as well as the warning bell are important improvements.

Mr. Staffel also exhibits a small mechanical machine for the performance of the addition and subtraction of fractions, whose denominators are 10, 12, and 15. By enlarging the machine, this number would be increased, and the power of the instrument extended. The operations were performed with quickness, and with accurate results. A Prize Medal was voted to Mr. Staffel.

THOMAS DE COLMAR (France, No. 390, p. 1196) exhibits the next best calculating machine in the Exhibition, and has combined the two essentials of economy of time and accuracy of results. It is adapted for the performance of the four first rules of arithmetic; and indirectly the square-root may be extracted by the knowledge of  $a^2 + 2ab + b^2$ , the results being inferred; but this is not the legitimate use of the instrument.\*

The instrument is adapted for the multiplication of numbers whose product is expressed by less than 16 figures; and consists of two rows of cylinders, the one containing 16, and the second 8; the former are moveable, the operation at each step being changed tenfold.

The principle of the instrument is, that multiplication is in reality the continual addition of itself as many times as there are units in the multiplier, and division that of continued subtraction of the divisor.

On trying the machine, the number 1 was almost instantaneously taken from 10,000, giving the difference, 9,999, accurately; the performance of this operation is generally a severe test to these machines.

The number 5,321 was multiplied by 3,256 in less time than was required to perform the calculation, in the manner following:—The number 5,321 was placed on one series of cylinders, and the number 6 was placed on one of the cylinders of the second row, and on the handle being turned (in one direction always) the number 31,926 appeared; the upper row was moved through one division, the handle again turned, and so on, till in a very short time, the number 17,325,176 appeared.

The several operations to which the instrument was subjected were performed quickly and accurately.

A Prize Medal was voted to M. Thomas De Colmar.

WERTHEIMER (No. 387, p. 451) exhibits several calculating machines, adapted for the performance of addition and subtraction of numbers and moneys, of this and of other countries.

Each machine consists of a box, with a metal plate divided into nine indexes, with semicircular notches, under which are placed a succession of holes. Round the indexes, numbers are engraved, and the semicircular notches are furnished with teeth, and a pointer to insert between the notches, for the purpose of bringing the notch opposite any particular figure, from right to left. This operation is dangerous, for the notch is liable to slip and not go home.

The instruments are ingenious, but they are much wanting if the essentials of such machines, viz., economy of time and unerring accuracy. The Jury, however, voted Honourable Mention to them.

\* For a description of this ingenious and useful machine, see the report of M. Benoit, "Au nom du Comité des Arts Mécaniques, Société d'Encouragement."

SCHILT (Switzerland, No. 59, p. 1270) exhibits a simple calculating machine, but which can perform the first operation of arithmetic only. Honourable Mention was voted to Mr. Schilt.

ROOKER (No. 340, p. 448) has exhibited a sliding scale of involution, the invention of Dr. Roget. The instrument consists of one fixed and one moveable scale, like a sliding rule. On the slide a line is logarithmically divided, the divisions of one half being from 1 to 10, and repeated on the second half in the same order.

The fixed scale is graduated in such manner, that each of its own divisions is set against its respective logarithm on the slider, and, consequently, all the numbers on the slider will be situated immediately under those numbers in the fixed scale, of which they are the logarithms. Thus, 3 on the fixed scale will stand under 100 on the rule, and so on.

The instrument is adapted to perform the operations of involution and evolution. The principle of the instrument is contained in the equation—

$$\text{Log. log. } a^x = \text{log. log. } a = \text{log. } x.$$

From the first member of which  $a$  disappears. Two differences of the second logarithms of the power and of the root being equal to the first logarithms of the index, it is evident, that if a scale of second logarithms be engraved on one line, and a first on a line sliding along it, the indexes being read off on the latter, the power will be so on the former.\*

LALANNE (France, No. 1690) exhibits a calculating rule, constructed upon new principles, consisting of a graphic table formed entirely of right lines, with which all calculations, usually performed by the sliding rule, can be performed to within 1-200th of the true result. The Jury awarded Honourable Mention to this Exhibitor.

#### *Instruments for the use of the Blind.*

HUGHES (No. 401, p. 452) has exhibited a portable typograph or writing machine for the blind.

This is a beautiful mechanical contrivance (by no means difficult in use) by which a blind person is enabled to print legibly, with ease and rapidity. It is also applicable to printing uniform labels for Museums, &c. (for description see "Illustrated Catalogue"). The following is the manner of using it. The paper intended to be written upon is placed within a portfolio, one side of which is made of semi-carbonized paper, which, being durable and inexpensive, serves for ink. Having done this with the first finger of the right hand, any required letter, figure, or point of the index circle is brought to the right side of the lever, the thumb being inserted in the end of which, presses it downwards. This pressure will give the impression of a corresponding type letter acting upon the back of the transfer paper. The next operation is to lift the lever to its utmost height, which motion makes the space required for the next letter, and so on to the end of a word. A repetition of the movement will also make the space between the words.

Having finished a line of writing, the index circle is pushed back to the left side of its frame, and the thumb-screw turned for the desired distance between the lines; one whole turn of this screw giving four lines to the inch.

The typograph is about the size of a quarto book, and does not occupy a surface of more than 12 inches square. Its inventor has done good service, having the merit of exhibiting the best machine for the same purpose, it being the most simple in its operations of any in the Exhibition. The Prize Medal was awarded to Mr. Hughes.

TOLLPUFF (No. 382, p. 451) exhibits a machine for facilitating the writing of the blind.

FOUCAULT (France, No. 220A, p. 1187) has exhibited a printing-machine for the blind. It consists of a fan composed of 26 rods, terminated at the upper extremity with the letters of the alphabet arranged successively, together with other rods terminated with the various ciphers and symbols required in printing; the lower extremity of these rods is furnished with a corresponding letter, &c., to

the one above, but in smaller type. On pressing the larger character at the upper extremity, the smaller letter beneath is proportionably depressed, which causes it to leave its printed impression on a paper previously prepared. By a little contrivance the paper is made to move onwards, in proportion to the successive pressures from above. The exhibitor of this machine, himself blind, has the merit of being its inventor, and he was awarded the Prize Medal.

THOMPSON (United States, No. 26, p. 1434) has exhibited an invention for teaching the blind to draw and write. This device is simple, and intended to afford a means to the blind of acquiring knowledge of various kinds.

The writing tablet is covered with white leather, a material well suited to the purpose intended, as it yields to the pressure of the style without retaining the impression.

The style may be made of any hard material capable of receiving and retaining a rounded smooth point. The paper should be of a strong and rather firm texture, but at no visit of the Jury was any explanation given, and they are unable to speak further of this invention.

GALL (No. 687A, p. 471\*) has exhibited a triangular alphabet for the blind. This is an improvement on the Parisian, Austrian, and other circular alphabets, and it is probable that adult blind persons may by its means be easily taught to read. A volume containing the Epistle to the Ephesians, in the same characters, was exhibited, and Gall's apparatus for the writing of the blind, by means of which they can correspond with each other by post, as described in the "Illustrated Catalogue."

MARCHESI (Austria, No. 139, p. 1049,) exhibits a circular printing machine, by which the blind can print readily with three different kinds of type. On examination by the Jury it elicited much commendation, and a Prize Medal was awarded to M. Marchesi.

#### *Miscellaneous.*

DUNIN (No. 210, pp. 433, 434) has exhibited a piece of mechanism designed to illustrate the different proportions of the human figure. This beautiful piece of mechanism resembles in outward appearance a well-formed human figure, standing erect. It is capable of both considerable expansion and contraction in all its parts. The internal mechanism is completely concealed, the figure externally being composed of a number of thin slips of steel and copper, which overlap each other in proportion to the amount of expansion or contraction exercised. The motion these slips are made to possess is communicated to them by thin metal slides to which they are attached within the figure, the slides being furnished with projecting pins at their extremities. These pins are inserted into curved grooves, cut in circular steel plates, the curvature of the grooves being so arranged, that when the steel plates are put in revolution by a train of wheels and screws, the slides belonging to the several parts of the figure are expanded or contracted in correct proportion. The external slips of metal are disposed as much as possible in the direction of the fibres of the muscles in the living subject, in which direction the two motions of contraction and expansion are severally performed. Where in nature the fibres of the pectoral muscle converge towards the shoulder, in the figure there is much compound internal mechanism, and very ingenious external arrangement; the contraction of the chest, the back, the shoulder, and the forearm, are performed either simultaneously, with great accuracy and just proportion, or each part can be separately adjusted if required. These adjustments, the most compound and difficult to be overcome, Count Dunin, by a new and most ingenious combination of mechanism, has successfully achieved. The dimensions of the figure are subjected to their respective variations by the establishment of a connection between several parts of the internal mechanism and a winding key, by means of circular-headed projections, which being turned to the right or left, gently and gradually effect the contraction or expansion of the adjacent parts of the figure. The motions we have just described, are performed by the introduction of the winding key into several

\* See "Philosophical Transactions" for the year 1815.

apertures left for its reception; one of them is situated immediately between the pectoral muscles on the chest; other apertures situated in the back, on the top of the shoulders, in the arms and legs, serve for the different adjustments required; about the knee of the figure, the movements of which are regulated by an aperture in the thigh, the workmanship and mechanical ability displayed are very great. The thin external metal slips, which overlap one another very considerably when the figure is quite collapsed or contracted, are each furnished with a long slit or cut-out groove, through which the pins from the plates beneath are seen to project; as these slips move easily over one another, it follows that when the figure is fully expanded, the slips can overlap one another scarcely at all; and thus the power of variation in the dimensions of the figure is dependent upon the individual length of these pieces of metal and their cut-out grooves.

The apparatus itself is not unlike in its general appearance to a fine suit of armour, displaying as it does the just proportions of the human form, deficient only in the extremities. The entire machinery is totally concealed, and works noiselessly, and though the entire mechanism is of the most compound nature, the whole is easily managed and adjusted. In addition to the general adjustments which we have described, we may observe that every part of the figure has an independent adjustment by which it can be put out of proportion, and made to represent the deformities or peculiarities of form of any individual.

We availed ourselves of an opportunity of carefully examining the interior of the mechanism of a similar figure in the work-room of Count Duin, it being impossible to obtain any correct idea of its internal construction from an external view of the figure as exhibited. This examination enabled us to form a high estimate of the genius and mechanical knowledge Count Duin has displayed in its construction. The mechanical combinations and parts employed are very numerous; they are as follows:—875 framing pieces, 40 grooved steel plates, 163 wheels, 202 slides, 476 metal washers, 4,828 spiral springs, 704 sliding plates, 32 sliding tubes (to assist in the elongation of some parts), 497 nuts, 3,500 fixing and adjusting screws, besides many other small pieces. The figure is maintained in its vertical position by means of a strong iron support at some distance from and affixed to its back.

The invention, which is stated could easily be made available in the artist's studio, is designed to facilitate the exact fitting of garments, especially where great numbers are to be provided for, as in the equipment of an army, or providing clothing for a distant colony, and will enable the personal attendance of individuals to be dispensed with, as from a new system of measurement the figure may be adjusted to the exact form and size of the person to be fitted.

A Council Medal was awarded to Count Duin for this beautiful piece of mechanism.

LLOYD (No. 322, pp. 444-446,) has exhibited a typhoidetor, or storm pointer, an instrument designed to determine, by inspection, the bearing and relative position of a revolving storm, or hurricane.

The instrument is composed of a ring of metal, upon which the several points of the compass are engraved; attached to the centre of the circle, around which it easily revolves, is a larger pointer, with the words "set this to the wind" upon its face; in addition to the pointer, two hands of a transparent horn are likewise made to move round the central point, one being designed for use in the northern, the other in the southern hemisphere; but both are intended to mark the ship's place. Each hand is perforated with a succession of small holes, for the adaptation of the instrument to charts of different scales. In the centre is a revolving glass, which, resting on a moveable centre and pivot, is made to revolve to the *left* when in the northern hemisphere, and to the *right* in the southern; it is designed to illustrate the revolution of the winds around their centre, and to determine the relative position of a ship to the centre of a storm.

It having been ascertained by Colonel Reid that storms have a progressive and revolving motion, and that on op-

posite sides of the equator they revolve in opposite directions, the centre of the storm being nearly a calm, it follows that the ship can be but in one position with regard to its centre, and that, in the event of the ship approaching the storm, or the storm approaching the ship, the edge or outer boundary of it must be first encountered.

For the purpose of affording to seamen a practical illustration of the revolving winds, circles showing the gyrations of a storm, with directions for use upon them, have been made on paper which, for convenience, has been rendered transparent; but these only prove useful in the case of a circular storm, and would fail entirely in a progressive whirlwind. Colonel Lloyd has the merit of supplying this want, and the Prize Medal was awarded to him by the Jury.

CHALLIS has exhibited an instrument for calculating the sum of the corrections of the three errors of a transit instrument, adapted for the latitude of Cambridge, and for any given N. P. D. The manner of determining these corrections is dependent upon certain geometrical considerations fully detailed in the "*Proceedings of the Royal Astronomical Society*," vol. x., No. 8. The instrument consists of a brass circular plate, moveable about a vertical axis, passing through its centre; on the plate are engraved lines for the purpose of taking account of both positive and negative corrections. At a short distance from the circular plate is a contrivance for guiding the motion of two bars, which carry two fine parallel threads of blackened unspun silk on the surface of the plate. The interval between the threads is made equal to the collimation error by means of a scale engraved on a brass plate, to which one of the bars is attached, and an index is fixed to the brass plate to which the other bar is attached; the two plates are clamped together by a screw; when the threads are set to the required interval, the screw-head serves for a handle by which to move them. The circle is graduated, for showing North Polar distances both above and below the pole. The method for performing the calculations and various details in the construction of the machine are fully described in the paper before referred to.

With regard to the degree of accuracy of which the machine is susceptible, Professor Challis observes, that for calculating the reduction to meridian transit, it has been usual to form a table of the coefficients of the collimation level and azimuthal errors, arranged according to the North Polar distance, whence the coefficient for a proposed N. P. D. may be readily deduced; for the sake of saving time, the multiplication having been performed by a sliding scale. The usual method may be inaccurate to one hundredth, or even two hundredths of a second, whilst the machine by moderate care will give the nearest hundredth of a second. The indications of the instrument, however, become more uncertain in proportion as the North Polar distances are less, on account of the small inclination of the threads to the correction scale; to meet these cases an additional scale is engraved, near the contrivance which gives direction to the threads.

Should the instrument be required for use in a latitude different from that for which it was constructed, a slight addition is required, but one which the instrument is made to perform itself. Professor Challis observes, that the machine, which requires no little nicety of work, was executed for him by Mr. Simms in a very satisfactory manner.

A Prize Medal was awarded to Professor Challis.

BLUNT (No. 372 p. 450) exhibits a model of Erastotheneus, as seen through a reflecting telescope of 9 inches aperture, 7 feet focal length, and magnifying power 380.

The model is beautifully executed, representing very accurately this part of the moon. The large crater-like cup, with the neighbouring mountains and smaller cup-like valleys in their neighborhood, are well shown. A Prize Medal was awarded to Mr. Blunt.

SPRATT (United States, No. 5, p. 1433) has exhibited lightning rods. These rods, in their cross sections, are similar to the letter X, and are made either of copper or of iron. The points are formed of a compound of platinum, silver, silex, antimony, bismuth, and tin, mixed in certain proportions. The extreme top being of solid

platinum is calculated to resist atmospheric decomposition. The base is furnished with three angular cast-steel magnets, plated with gold, one being also affixed to the brass connections at every point, for the purpose of facilitating the silent discharge. Zinorings are placed between these joints to prevent oxidation.

The fastenings and glass insulators, also exhibited, are designed to afford greater convenience for the attachment of the lightning rods. Owing to this invention being in process of registration, the Jury were not able to examine it at the proper time.

NASMYTH (No. 688, pp. 471\*, 472\*) exhibits a well-delineated map of the moon on a large scale, which is drawn with great accuracy, the irregularities upon the surface being shown with great force and spirit; also separate and enlarged representations of certain portions of the moon as seen through a very powerful telescope; they are all good in detail, and very effective. A Prize Medal was awarded to Mr. Nasmyth.

FISHER (United States, No. 263, p. 1452) has exhibited a "dial of the seasons," intended to illustrate the sun's declination at all seasons, together with the coincident effects of light and heat upon animal and vegetable life in all climates.

The chart is divided into two portions by a line crossing the picture horizontally. The upper corner to the extreme left is made to serve as the apex of the triangles, formed by lines drawn from it to the boundary line; these, by their verticality over the tropics, and gradually increasing obliquity towards the Polar regions, illustrate very clearly the different amount of sun-light distributed over equal degrees of latitude, and the difference of temperature consequent upon this unequal distribution. The chart gives also a comparative view of the equinoctial and solstitial angle of sun-light, and is designed to show the comparative rapidity of the sun's declination at the spring and autumnal periods of the year.

The effect of the unequal distribution of sun-light is shown by a series of coloured illustrations, placed immediately beneath the boundary line, which, forming the base successively of the various angles, becomes in a measure graduated. The several degrees of latitude between these graduations contain the principal productions, either animal or vegetable, which may be considered strictly indigenous: thus, towards the equator, are shown the palm-tree, the coffee-plant, the tiger, &c.; in the polar regions to the north, the white bear, pine-tree, Laplander, &c.; whilst the temperate latitudes are characterized by the various animal and vegetable productions with which we are most familiar. Immediately beneath these illustrations is another parallel series, representing on the ocean the corresponding ranges of temperature from the tropics to the poles; indicated by the typhoon in its progress, the storm of the temperate latitudes, aurora borealis, the volcano of Mount Hecla, &c. The chart, which is carefully executed, and well suited for educational purposes, is 2 feet 9 inches by 1 foot 4 inches. The book accompanying it is of considerable length, but too diffuse for educational purposes. It contains a detailed description of the diagram, and towards the conclusion an interesting table showing the influence of climate upon intellectual development, confining the existence of men of genius to within certain parallels of latitude: it is pleasingly and well written, and, were it within our prescribed limits, fairly entitled to a favourable review.

LEYSER (Saxony, No. 16, p. 1105) exhibits Weber's electro-dynamometer for measuring the intensity of galvanic currents.

The instruments employed by Ampere in his electro-dynamical researches are not capable of affording very accurate results from the friction overcoming, either wholly or in part, the electro-dynamic force to be measured. Under the most favourable circumstances the utmost that these instruments can perform is to enable the feeble electro-dynamic forces to overcome the friction; but in every accurate measurement it should be assumed that the friction is an insignificant fraction of the force to be measured.

In order to exclude friction the electro-dynamometer was contrived by Professor Weber. It consists essentially

of two coils of wire covered with silk; one of these has 650 feet of copper wire, making 1,300 turns round a slender ivory spindle, 0.79 inch in length, and 1.26 inch in diameter. The ivory spindle on which the coil is wound is attached to a slender stump of brass, which carries a circular plane mirror about 1.1 inch in diameter, and also an index about 1.1 inch in length, beneath which is a circle having a graduation of about the same diameter. The two ends of the wire forming the coil are attached to the lower ends of two fine silver wires 19.7 inches, and 1.27 inch distant from each other, by which the stirrup and coil are suspended, with the axis of the coil horizontal, like the bifilar magnet, for measuring variations of the horizontal component of the earth's magnetism. The second coil has 980 feet of wire, making 900 coils round a thin hollow brass cylinder 1.73 inch in diameter, and 1.73 inch in length, placed with its axis horizontal, bisecting, and bisected by the axis of the suspended coil. The two coils are surrounded by a case having an opening, covered with plate-glass, through which the mirror attached to the suspended coil can be viewed. A vertical glass tube, 1.65 inch in diameter, and about 19.7 inches in length, ascending from the middle of the case, carries at its upper end insulated attachments for the upper end of the suspended wires, with adjustments in height and distance from each other, and a motion round the axis of the glass tube.

The case is fastened to a circular plate 5 inches in diameter, which has an azimuthal motion on a pedestal 6.7 inches in diameter, provided with 3 foot screws for horizontal adjustments. The upper end of one of the suspending wires is connected by a conducting wire with one end of that of the fixed coil; the upper end of the other suspending wire is connected respectively with the poles of a voltaic element or battery; the current will hence traverse the whole of both the fixed and suspended coils. At a proper distance is placed a horizontal paper scale of 19.7 inches, the image of which, by reflection, is seen in the mirror attached to the suspended coil, and viewed through a telescope placed immediately below the scale, so that the angular displacement of the suspended coil, produced by the mutual action of the currents traversing the two coils, can be measured with great precision.

By means of an instrument similar to that exhibited, Weber obtained a most accurate experimental proof of the mutual action of voltaic currents on each other.

The electro-dynamometer serves to measure the intensity of a voltaic current, as does a magnetometer under the influence of a coil through which the voltaic current is transmitted; but the electro-dynamometer differs from the magnetometer in some very important particulars, the one supplying many of the deficiencies of the other.

In the magnetometer the tangent of the deviation is proportional to the intensity of the current; in the electro-dynamometer it is proportional to the square of the intensity of the current.

A change in the direction of the current causes the magnet to move to the other side of its position of equilibrium; when not acted on by the currents it does not affect the position of the electro-dynamometer.

The electro-dynamometer has been employed by Mr. Weber to measure the intensity of the oscillations producing sound. By including a magnetometer and an electro-dynamometer in the same circuit, he was enabled to determine both the duration and intensity of momentary currents, such as those produced by the discharge of a Leyden jar. Results, highly valuable as determining the effects of momentary streams in animal physiology, may be obtained by similar observations.\*

The instrument is exhibited by Leyser, to whom much praise is due, not only for the workmanship, but also for many details which he has introduced in its construction.

ENGEL (Berlin, Prussia, No. 274, p. 1065) exhibits a well-executed wood model of Fresnel's wave surface, in vial crystals, and an ellipsoid of three unequal axes marked with the lines of curvature. A Prize Medal was awarded.

\* See Weber's "Elektro-dynamische Maassbestimmungen, insbesondere wider stands messungen;" Leipzig, 1850: and also Poggendorff's "Annalen," B. 73, S. 193.

WARD (No. 664, pp. 466\*, 467\*) exhibits his botanical cases, which are fully described in the Illustrated Catalogue. A Prize Medal was awarded to him.

DE LA RUE (Class XVII., No. 76, p. 542) has exhibited various applications of iridescent films for the purposes of decoration, their vivid colours being produced simply by the agency of light upon a thin, transparent film of varnish. The process adopted to render the film and its reflected colours permanent, together with the method of its applications, are as follows:—

The objects to be ornamented, whether insects, shells, birds, bronzes, paper-hangings, card-cases, &c., are immersed in a vessel of water. Upon the surface of the latter, when perfectly tranquil, is dropped a little oil or spirit varnish, which, spreading in all directions, becomes exceedingly attenuated, and reflects the most vivid colours of the spectrum. The varnish being fixed, the object, which is slowly raised in such manner that the film shall adhere to its surface, is then placed in a convenient situation, to permit the water draining off. When completely dry the film is found to be firmly attached, and perfectly iridescent, having lost nothing of its original brilliancy of colouring. This is a beautiful illustration of the production of colour on a thin transparent surface, by the slight agency of light, such as is transiently seen in an ordinary soap-bubble. The Jury awarded a Prize Medal to Mr. De la Rue.

VAN SCHENDEL (Belgium, No. 173, p. 1157) exhibits an exceedingly good illustration of the laws of perspective, consisting of a series of objects, of exaggerated forms and dimensions, painted upon a horizontal plane, and two vertical planes. At a certain height above the picture there is a circular hole, cut in a small wooden frame; on looking through which, the objects assume a natural appearance, in strict accordance with the rules of perspective, and appear in the most perfect relief. A Prize Medal was awarded to Mr. Van Schendel.

FISHER (United States, No. 263, p. 1452) has exhibited "mathematics simplified," consisting of some beautifully-drawn diagrams, intended to facilitate the study of mathematics. His idea is that of teaching a physical geometry, either preliminary to, or, when no better may be had, instead of the science. His method of using the diagrams is by teaching each step by a course of reasoning, and illustrating the laws by well-drawn figures.

Nobody can question the great disadvantage under which students lie who have to apply geometry graphically, if their previous figures have been drawn only by hand; or, what is worse, if badly drawn by ruler and compasses. It is doubtful which of the two is the greater evil: the giving a student ruler and compass as part of his course of geometry, or the making reasoning on badly-drawn figures the only preparation for a draughtsman or architect, &c. This has been often said, but seldom accompanied with any proof of the very satisfactory use which may be made of well-drawn diagrams. Mr. Fisher has the merit of offering this proof to the Exhibition, with some ingenious ideas as to the manner in which the details may be managed. The attention he has paid to one point, viz., the exhibition of areas of given simple ratios under the same and different forms is particularly beneficial. Some of his diagrams are, in this respect, excellent studies for an eye which is to be trained to correct estimation. His method is particularly applicable for adults possessed of a power of thought, which requires to be enlisted and exercised to make their study agreeable or even profitable.

Mr. Fisher's merit may be described as consisting in—1st, the application of the idea of teaching by physical perception, to a wider range of subject than merely making very exact drawings of the propositions to be demonstrated in Euclid; 2nd, in the ingenuity of his details; 3rd, the beauty of the drawings. The Jury considered Mr. Fisher deserving Honourable Mention.

PERIGAL (No. 693, p. 472\*) has exhibited a demonstration, by the transposition of parts, of the theorem of the right-angled triangle. The square or base of a right-angled triangle being intersected by two straight lines, passing through its centre, parallel and perpendicular to

the hypothenuse, is thereby divided into four parts equal and similar to each other: which, being symmetrically arranged around a square equal to that on the perpendicular, form therewith a square equal to that on the hypothenuse of the right-angled triangle conversely. The sides of the hypothenuse square being bisected, and the points of the bisecting lines being drawn (till they meet) parallel to the base and to the perpendicular, the hypothenuse square is thereby divided into four equal quadrilaterals, which are together equivalent to the square or the base, encompassing a square equal to that on the perpendicular. Thus proving that "in a right-angled triangle the square of each side is equivalent to the *sum*, or to the *difference*, of the squares of the other two sides."—*Euclid*, i. 47.

Mr. Perigal has also exhibited a quadratic trisection of the square. The square is divided into nine parts of three different shapes and sizes; so proportioned that, by combining together one of each of them, they will form three equal squares, each one-third the area of the square formed by the whole nine sections. The construction is scarcely susceptible of brief explanation without a diagram.

Mr. Perigal likewise exhibits diagrams of the *retrogressive* parabola, as derived from the circle,  $y = R \cos \phi$ ;  $x = R \cos 2 \phi = R (2 \cos^2 \phi - 1)$ .  $\therefore 2 y^2 = R (R + x)$ . The origin of co-ordinates at centre of circle, radius  $R$ . The kinematic curve, of which the retrogressive parabola is a limit, was discovered by Mr. Perigal, in 1835, and produced from continuous motion by him in 1840.

Mr. Perigal has also exhibited a lunarian, of novel construction, which he calls a "selenoscope;" intended to elucidate the kinematic effects of the three hypotheses which have been advanced to account for the inhabitants of the earth never having seen more than one-half the surface of the moon, the same hemisphere of our satellite, being always presented towards the earth. For this purpose, a terrestrial globe (about 3 inches diameter) is fixed on a brass stem supported by a brass pedestal. At the bottom of the stem is a fixed wheel of forty-eight teeth; and, between that and the pedestal, a T-shaped brass arm is centred, having at one end a receptacle for a mariner's compass. The other extremity of the arm is grooved to receive four arbors with each a wheel of forty-eight teeth like the fixed wheel first mentioned, into which one of them is made to gear. Another wheel in the middle of the cross part of the T gears into the second, and a fourth at the extremity into the third; while the fifth occupies a position at the opposite end of the cross groove, but does not gear with the other wheels. All these wheels have the same number of teeth. To the third, fourth, and fifth wheels are attached spindles, each carrying an ivory ball (about one inch diameter), representing the moon, at such elevation that their centres and that of the globe, representing the earth, may be all in the horizontal plane.

Carried by the arm round the fixed wheel, into which it gears, the second wheel is constrained to turn round its axis or arbor in the same direction, driving the third wheel in the contrary direction, by which the fourth wheel is driven in the same direction as that of the revolving arm; all with the same angular velocity; while the fifth wheel, not being in gear with the others, revolves with the arm without any additional rotation on its own arbor or axis. A coloured spot upon each of the ivory moons tends to render their relative motions more perceptible and distinct.

By this means one of the moons is caused to rotate on its axis in the same time, and in the same direction in which it revolves; another is caused to rotate on its axis in the same time in the contrary direction to which it revolves; while the third moon revolves about the earth, but does not rotate round its own axis.

Mr. Perigal also exhibited a gyroscope; an instrument designed to illustrate the effects of revolution and rotation. On a brass pedestal, an arm, supported at one end by an axis round which it freely revolves, carries at its other extremity a globe (about one inch diameter) representing the earth or the moon; which is flange-jointed in the middle, in order that the globe may be placed over

the axis or centre of motion, and at various distances, as the experimenter requires.

GERARD (No. 109, p. 418) has exhibited a spherical trigonometer, for the mechanical solution of problems in spherical trigonometry and nautical astronomy. The instrument consists of three legs, jointed together nearly as in the common triangular compass, and in such manner as in every position to point to a common centre, and to represent three radii of a sphere; three graduated arcs form the sides of the spherical triangle. In use an angle is measured by clamping a brace upon the sides containing it, and sliding the other to 90° upon three sides. The instrument is coarsely constructed, but its principle is good, and if better made would be very useful; the Jury consider it well deserving Honourable Mention.

DEMANET (Belgium, No. 178, p. 1157). Conversion of vibrating into rotatory motion. This is done by the inertia of a bob-weight on a horizontal arm attached to an axis which has a fixed bearing below, and can be pushed or pulled backwards and forwards from above. The bob once set going is its own crank and fly-wheel. A sudden push given to the axle crosses the bob in the same direction, and the axis being then held till the bob by its inertia has attained the other side, the axis is pulled, and then the bob gets a further motion: by means of alternating the action and non-action of the axis to coincide with favourable situations of the bob, it is made to obtain a rotation, which is easily maintained by a regular to-and-fro movement of the axis, whose upper end works in a gimbal, and is guided in its motions by a groove.

YATES (No. 378, p. 451) exhibits an instrument for squaring the circle. Its principle is, that the diameter of a circle multiplied by 1.25, equals the diagonal of the square required.

ROBERTS (No. 130, p. 422) has exhibited a synchro-nometer. It consists of a gutta-percha tube, connecting two expansions of the nature of bellows, of vulcanized Indian-rubber; on expanding one of these by a spring worked by an eccentric wheel in connection with any movement, a partial vacuum is created, which being propagated along the tube, sucks in and closes down the other, whose movement puts in action a click acting on a ratchet-wheel. Thus every movement of the mechanism at one end of the tube may be synchronously (or very nearly so) communicated to a corresponding mechanism (as a clock) at the other.

COOKE (No. 664A, p. 467\*) exhibits closed cases for plants.

BATMAN (No. 187, p. 430) exhibits a machine intended to illustrate the effects of centrifugal force. It consists of a representation of the planet Saturn, attached to a piece of string by the edge of its ring, which, when in a state of repose, is in the same straight line with it, but on a rapid twisting motion being communicated to the string by clock-work, the object occupies a position at right angles to the string, or, in other words, spins round upon its shorter axis.\*

DARNELL (No. 383, p. 451) exhibits an apparatus for the detection of either fire or robbery; consisting of a lever, with a centre tumbler and balance weight, which is poised by a small line carried through any portion of a house, and fastened. On the least pressure the balance weight is raised; or if the line be cut or burnt, it will fall into a notch; in either of which cases, the alarm is put in motion. It is contained in a small portable box.

SAUNDERS (No. 205, p. 433) exhibits a Kaleidoscope which revolves on pressing the covering of the eye-piece downwards, and, therefore, is self-acting whilst the instrument is in use. This is the only kaleidoscope exhibited.

KNIGHT and SONS (No. 453, pp. 462, 463) exhibit a machine for cleaning and polishing daguerreotype plates; portable mercury box; plate-holders; head-rests; with a series of bolt and socket joints; glass and porcelain dishes for preparing sensitive paper.

\* See Dr. Parr's "Philosophy of Motion" for a distinct description of this machine.

THOMSON (No. 80, p. 417) exhibits an instrument called an autochronograph, intended for the registration of the times of occurrences; for example, to register the time of the arrival and departure of trains in railway stations, &c.,—to note the presence and individuality of guards, and other persons whose absence might incur inconvenience or danger; it is thus of use also in police and public offices, banking and mercantile houses, &c.

DYER (No. 370, p. 451) exhibits a circular slate, divided into as many equal portions as there are days in the month. It is intended to make memoranda of engagements, &c., that occur on each day; and when properly adjusted at the end of each month, and turned day by day, each day's engagements are brought correctly under notice.

ROVER (No. 197, p. 431) contributes Lawson's observing chair, to enable astronomers to observe with large telescopes.

WATKINS and HILL (No. 659, p. 456\*) exhibit Biot's apparatus for the polarization of liquids; a reflecting polariscope; an oxy-hydrogen polariscope; Attwood's machine; and a steam-engine indicator, for ascertaining the power of steam-engines.

NEWBERRY (No. 460, p. 464) has exhibited a case of medals, the metal precipitated by electro-metallurgy, containing—a medal of Alfred the Great; Clement XII., from a very scarce original; Pius V., from the original in the possession of the exhibitor; and various others.

RUXDELL (No. 438A, p. 461) exhibits impressions of seals, the depth and execution of which are very good, as are the ciphers and arms, particularly when it is considered that they have been executed by machinery.

WILLATTS (No. 265, p. 437) has exhibited a registering thread counter, or linen prover, a small instrument designed for the purpose of ascertaining the number of threads in a certain sized piece of linen or silk, by means of an index and a self-registering apparatus. A magnifying lens is also attached, for examining the texture of the material to be tested.

HAWARD (No. 298, p. 442) has exhibited a gauge for measuring the thickness, and ascertaining the weight of metal and other plates, rods, and bars. Its principle is the progressive movement of a most accurately cut screw, to which is affixed a dial or circular index, so divided that each space indicates the advance of the screw to the thousandth part of an inch. The gauge exhibited is so divided that each of the smaller divisions represents one ounce per foot of superficial sheet iron, whose specific gravity is 7.68, with other divisions, till a weight of 20 lbs. to the square foot is shown. This gauge is convenient in use, and Mr. Haward has very wisely adopted the decimal notation in the subdivision.

EDGE (No. 702, p. 473\*) exhibits a photometer for the determination of the illuminating power of gas, as compared with that derived from any other source. The instrument was not tried by the Jury.

CHAMBERLAIN (No. 399, p. 452) exhibits a large model of a machine for recording votes, which is so constructed that the vote shall be recorded without the manner of its disposition being made known, the number of votes given being indicated by the sounding of a bell. The machine appears to be well adapted to the purpose intended, and combines ingenuity of construction with careful workmanship. Being an instrument intended for direct use, it does not fall within the province of this Jury, and was not subject to an award in Class X. This notice is given in consequence of its being placed among philosophical instruments.

BAKER (No. 396, pp. 451, 452) has exhibited a vacuum gauge, furnished with a sliding scale, the glass tube being protected by a bronze covering. Also a vacuum gauge, fitted in a brass case, showing a scale of more than 22 inches, and is intended for sugar boiling, and for situations where space is an object. A steam-gauge upon the principle of compressed air, to show the temperature of steam at various pressures. Another steam-gauge, so constructed as to be less easily deranged by carriage from place to place.

BROWN (No. 435, pp. 446, 447) has exhibited a patent power-engine, which acts as a water-meter. Its novelty

consists in its economy of space; it is 3 feet in height, 2 in length, and 2 in width. He also exhibits a patent water-meter, which is 2 feet in length, 2 in width, and 1 foot 6 inches in length; stated to keep perfect adjustment under varying pressure. Also a patent water-meter, stated to work in compressed air, without cock or valve; and two other meters. (See the Illustrated Catalogue.)

LAWRENCE (No. 115, p. 418) exhibits a screw-wrench, capable of being adjusted by a spring, and of being varied in size in a moment. Also a pair of dividers; a hand-drill, intended to supersede the use of the bow-drill, and driven by a crank. A turner's centre-bearing, with friction-rollers to prevent small articles from moving in the lathe, and to enable the lathe to turn easier than in the ordinary way. These articles all seem to be useful, but scarcely belong to Class X.

PLANT (No. 215, p. 434) has exhibited a self-registering steam-boiler feeding apparatus, intended as a substitute for the common force-pump and regulating-float.

ROCHER (France, No. 991, p. 1226). A tank apparatus, for the distillation of water; adapted to the use of a ship of the line. The workmanship is excellent, but it can, in no respect, be considered a philosophical apparatus.

GUCKEN (No. 446, p. 462) has exhibited damp-detectors, fitted up in different kinds of boxes; also several angle-meters.

MERRYWEATHER (No. 151, p. 429) has exhibited a tempest-prognosticator. This consists of a number of bottles placed on an ornamental stand, in each of which it is proposed to place a leech, so as to render available the well-known sensitiveness of this animal to changes of the weather.

Before closing this Report, it may be well to dwell for a short time upon the probable good resulting from the exhibition of the subjects which it embraces. So vast is the field over which it is spread, and limited the time allowed for its preparation, that, in some instances, we have been able only to enumerate, without fully discussing, the merits of individual works. No opportunity, for the same reason, is afforded of instituting an inquiry into the comparative importance of the several classes of instruments—an inquiry which would be attended with great labour, from the necessity of gravely weighing and determining the comparative value of results which we have been enabled simply to record.

That the Exhibition will form an era in art and science is to be expected; and that both will benefit greatly from so large a collection of instruments and useful applications from all countries is also certain. That it is not calculated to engender national animosities will be seen by a review of our Report, which discovers the fact, no less pleasing than anticipated, that every country is characterized by peculiar excellence in some department; and we might venture to predict, that steady and constantly progressive as the advancement of science has been—from the broad basis now offered for the first time, as a groundwork for future improvements—it will receive a fresh impulse and many accessions from new and otherwise unexpected quarters. That the Exhibition has

received contributions from individuals of various grades, is one of its most pleasing features; as is the fact that a vast field for increase of knowledge, and a means of self-education, has for the first time been opened to the artisan. This class of individuals greatly want a knowledge of that which has been done—a deficiency the Exhibition is well calculated to supply, and may thus divert much fruitless labour and ingenuity into newer and more useful channels. That there does exist in this class of the community a considerable amount of ability and power of application, is evidenced by the various patents which have been taken out for ideas and inventions, the purchase-money of which has too often been the sole remuneration of the inventors.

The Exhibition will make the improvements which have been made in different instruments by various countries known to all; and the means for the acquisition of knowledge, hitherto confined to the few, will, by it, be placed within the grasp of the many.

Glancing once more at the collection now before us, combining as it does a concentration of the labours of eminent men, who have toiled during successive generations for the advancement of science, and whose successful efforts have developed the important principles which have served for the groundwork of modern discoveries, and their beautiful applications to the wants of the present day, we are impressed more strongly than ever with the all-important fact, that much as man has done, both in the physical and scientific world, by a long train of brilliant discoveries, there is more yet left to achieve than has hitherto been accomplished.

As heat, light, electricity, magnetism, chemical affinity, &c., by the recent discoveries of Volta, Faraday, Oersted, Seebeck, Wheatstone, &c., have been found to be mutually related, so that heat may be said to produce electricity, and *vice versa*, and so on for all the rest, we may expect that a still more intimate union than that already discovered may be found to exist. That things apparently distinct and remote prove to be linked together and inseparable, is instanced by the frequent discovery of intermediate missing links in the continuity of the chain connecting all living bodies, from the most minute, and almost inappreciable, to man; and which have tended to prove that the powers with which they are severally endowed, and the principles of their formation, have been regulated upon one grand system of gradation, having unity alone for its summit. That the effect of a concentration of the sciences of the age must be infinitely greater than that exerted by a single one, is obvious; as also that this concentration and union, once effected, will be productive of vast and universal applications, such as we dare not even to predict.

The Exhibition, by collecting, within a comparatively small space, almost all the known applications of science throughout the civilized world, is eminently qualified for the attainment of this great end, by promoting the advance of science in its various branches, and by infusing a taste for the development of the highest faculties with which man is endowed.

JAMES GLAISHER, REPORTER.

*Lewisham, Nov. 1851.*

# INDEX TO CLASS X.

NOTE.—This Report being so extensive, and embracing a large variety of subjects, it has been deemed by the Author expedient to prepare a special Index to accompany it.

## INTRODUCTION, 243.

*Subjects included in Class X., 243.*

ASTRONOMICAL INSTRUMENTS, *their construction and workmanship, 243.*

ELECTRO-MAGNETISM, *its application to the simultaneous registration of astronomical observations, 243.*

NAUTICAL AND SURVEYING INSTRUMENTS, 243.

OPTICS; *improvement of optical glass; microscopes; physical optics; lenses and prisms, 243.*

PHOTOGRAPHIC CAMERAS, *and their improvement, 243.*

PHOTOGRAPHY; *its utility; future importance; present improvement as illustrated by the Exhibition; in connection with art, as applied to the purposes of illustration; its application to science; to astronomy; to the self-registration of natural phenomena; to literature, 243.*

PHOTOGRAPHS of America, France, England; *their characteristics, 244.*

*M. Marten's calotypes; Claudet's improvements; Ross and Thomson's new process, 244, 245.*

*Positives on glass; probable causes of rapid advance of photography, 245.*

*The late M. Daguerre, 245.*

ELECTRIC TELEGRAPHS, 245.

ELECTRO-MAGNETS, 245.

MAGNETO-ELECTRICITY, 245.

ELECTROTYPE application of Voltaic action, 245.

CHEMISTRY AND CHEMICAL APPARATUS, 246.

FIRE ANNULATORS, 246.

PLANIMETERS, 246.

AIR-PUMPS, 246.

STANDARD MEASURES OF LENGTH, 246.

CALCULATING MACHINES, 246.

INJURIOUS EFFECT OF PATENTS, *how exemplified, 246.*

CLASSIFICATION OF THE REPORT, 246.

PROBABLE OMISSIONS, 246.

## ASTRONOMICAL INSTRUMENTS, 246.

*Probable cause of the omission of large instruments, 246.*

*Excellent workmanship, 246.*

*Avoidance of unnecessary screw connections, 246.*

*Mr. Simms's improvements, 246.*

*Workmanship of the German instruments, 246.*

*The process of dividing by hand objectionable, 246.*

*Superseded by machinery; the advantages of the latter method; graduation of the Westbury circle, 246.*

*Mr. Bond's electro-magnetic apparatus, 246.*

DOLLOND. Variation transit instrument, 246.

SIMMS. Transit instrument; its object-glass; conversion of the axis into a telescope; adjustments; eye-pieces, 247.

SIMMS. Diagonal transit; mode of illumination, 247.

GERARD. Field transit instrument; its construction, 247.

DOLLOND. Double altitude instrument, 247.

SIMMS. Transit circle; its graduations; supports; illumination, and its advantages, 248.

ROSS. Large equatorial; dimensions; support; construction, 248.

SIMMS. Equatorial; its dimensions, &c., 249.

SIMMS. A small equatorial, without clock motion, 249.

DOLLOND. Portable equatorial, 249.

SIMMS. Westbury circle; graduation; microscopes; axis; object-glass, 249.

SIMMS. Altitude and azimuth instrument; its construction; adjustment and novelty, 250.

CRICKETT. Model of an equatorial stand, 250.

ERTEL AND SONS. Universal instrument; particulars of its construction; new application of its clamps; object of the designer; its successful attainment, 250.

Professor Miller's remarks on application of clamps at the centre, &c., 250.

MERZ. An equatorial; its telescope and workmanship; tests to which the telescope was subjected, 251.

BOND. Apparatus for recording transit observations by means of the touch; its principles explained, 251.

NAUTICAL INSTRUMENTS; their number and respective merits, 252.

## NAUTICAL ASTRONOMICAL INSTRUMENTS, 252.

SIMMS. Troughton's reflecting circle, 252.

SIMMS. Troughton's sextant, 252.

BARRETT. Sextants, 252.

CRICKETON. Sextants, 252.

TAYLOR. Sextant, 252.

ELLIOTT AND SONS; WATKINS AND HILL; DIXEY. Sextants, 252.

MOLTENI AND SIGGIER. Sextants and reflecting circles, 252.

VEDI. A reflecting circle; improvements by Captain Richards; several sextants, 252.

BURTON. Sextants and octants, 252.

BEAULIEU. Sextants, 252.

OERTLING. Sextants, 252.

IMPERIAL JOURN WORKS. Two large sextants, 252.

ASHIE. An instrument for great circle sailing, 252.

## VARIOUS NAUTICAL INSTRUMENTS, 252.

ERICSSON. A sea-lead; description, 252.

ERICSSON. An instrument for determining distances at sea; description, 253.

KELLER. A double planisphere, 253.

St. JOHN. Detector compass; aquatic velocimeter, 253.

## SURVEYING INSTRUMENTS, 253.

*Introductory remarks; comparison of respective excellences, 253.*

## SURVEYING AND LEVELLING INSTRUMENTS, 253.

SIMMS. Transit, theodolite; application; dimensions, power, &c., 253.

DOLLOND. Transit theodolite; description; illumination of the lines, 253.

YEATES. Portable theodolite; theodolite; prismatic compass; optic square; workmanship, 253.

MARRATT. Theodolite; construction to avoid flexure, 253.

JOSEPH. Theodolite, 254.

ELLIOTT AND SONS. Altitude and azimuth instruments; construction; theodolite; levels; adjustments; instruments for the determination of distances, 254.

BRIDGES. Instrument for the determination of distances; rules and conditions for its use, 254.

BARTON. Instrument for sketching; object of its design, 254.

JIDDLY. Sights; levels; construction, 254.

ADCOCK. Drawing-machine, 254.

GREEN. Miner's compass, 254.

COX. Beam draining level; construction and use, 254.

BLYTH. Levels, 254.

DOBBS. Spirit level, 254.

HORNE, THORNTWHAITE, AND WOOD. Spirit level; use and adaptation, 254.

DENTON. Draining levels, 254.

WILTON. Miner's theodolite, 254.

BURON. Theodolite; dimensions; levelling instruments, 254.

BEAULIEU. Theodolite, similar to Gambey's dimensions, and adaptation; workmanship, 254.

GROETIERS. An instrument for determining distances, 254.

DE HENNAUT. Miner's compass, 254.

LAMBERT. Miner's compass, 254.

BECKER. Levelling apparatus, 254.

- BREITHAUPT.** Theodolite; mode of graduating; protection of the vernier circle by glass; level; peculiar construction; mining theodolite; description, 254.
- LUTTIG.** Levelling protractor, 255.
- KINZELBACH.** Surveying cross; description; diastimeter; Wollaston's goniometer, 255.
- IMPERIAL POLYTECHNIC INSTITUTE OF VIENNA.** Level; construction; improvements; adaptation; small levels; pocket levels; rulers for plane table surveying, 255.
- SCHRODTER.** Theodolite, 255.
- IMPERIAL LONSK WORKS.** Levelling instruments and stand; workmanship, 255.
- BORT.** Astronomical compass; construction; adaptation; 255.
- STANDARD MEASURES OF LENGTH, 255.**
- WHITWORTH AND CO.** Standard bar measure; construction; powers; how applied; description of tests; suggestions for improvement, 255.
- BAUMANN.** Bessel's standard measure; construction; mode of making comparisons; delicacy; elimination of error, 256.
- SIMMS.** Standard yards; methods of support by Professor Miller and Rev. R. Sheepshanks; comparison of relative merits; standard scales, 256.
- DIVIDING MACHINES, 257.**
- ACKLAND.** Dividing machine; usual method of graduation; Mr. Ackland's method divided into three processes; description; example, 257.
- PERREAU.** Line divider; principle and construction, 257.
- FROMENT.** Divided metre; Froment's screw; application of electricity, 257.
- CONSERVATOIRES DES ARTS ET METIERS.** Gambey's brass metre; platina metre; description; standard kilogramme; French coins of legal currency; measuring rods and chains; measures of capacity, 257.
- BALANCES, 257.**
- Introduction; varied nature of collection; beauty of workmanship; Fox's balance; enumeration of the various modes of construction not adopted; Wollaston's method of checking oscillation the most simple and efficient; division of the scale, 257.*
- LUDWIG ORTLING.** Balance; beam coated with palladium; balance to carry one kilogramme in each pan; description, 258.
- DOVER.** Balance; workmanship equal and similar to that of Robinson; mode of adjustment; substitution of links for silk threads, 258.
- FOX.** Balance for small weights; adjustment of the beams by magnetism; method of overcoming friction, 258.
- MARRIOTT.** Chemical balance; construction of the beam; peculiarities, 258.
- DE GRAVE, SHOOT, AND FANNER.** Assay balances; commercial balances; weights; measures of capacity, &c., 258.
- BACHE.** Large balance; construction and adjustment; small balance, 258.
- DELEUIL.** Balance; avoidance of screw adjustments; adapted for weighing gases; chemical balance; remarks upon construction; assay balance, 259.
- COLIOT.** Balance; assay balance, 258.
- BÉRANGER.** Balances for the counter; steelyard; double steelyard; model of a machine for determining pressure; *Peso compteur*, or weighing-machine; reason for not awarding a Medal to M. Béranger, 259.
- SACRE.** Balance; construction; its peculiarities; suspension of the pans; beauty of workmanship; assay balances, 259.
- ORTLING.** Balance; construction and mode of adjustment; attachment of two thermometers; their position objectionable; two small balances, 259.
- REIMANN.** Balance; mode of effecting the adjustment of the knife edges; adoption of the circular level, 259.
- HOFFMANN AND EBERHARDT.** Balances for apothecaries, 259.
- LUHME.** Chemical balances; their capabilities, 259.
- BATKA.** Kusche's small balance, 259.
- DOLBERG.** Balance; mode of checking oscillation objectionable, 260.
- BECKER.** Balance; construction, 260.
- NISSEN.** Large balance; form of scale-pans objectionable; small balance; assay balance, 260.
- LITTMAN.** Balance; substitution of an additional index, for a graduated scale considered objectionable, 260.
- VIBERG.** Chemist's balance, 260.
- COIN-WEIGHING MACHINES, 260.**
- Difficulties attendant upon the old method of weighing the gold coin; dissatisfaction of the public; difficulty of weighing with sufficient accuracy; causes as discovered by Mr. Cotton enumerated; overcome by Mr. Cotton's coin-weighing machine; success attendant upon its use, 260.*
- Description of Mr. Cotton's machine; construction; mode of acting detailed; saving of revenue effected since its use was established in 1844, 260.*
- SMITH.** Coin-weighing machine; its principle and construction, 261.
- DELEUIL.** Coin-weighing machine, designed by Baron Segnier; conjectural description of the construction; the machine not being patented, the internal mechanism was not examined, 261.
- Suggestions by Sir John Herschel for the construction of a coin-weighing machine, 262.*
- Collection of balances in the Exhibition satisfactory; remarks upon the omission of self-weighing machines for small weights, 262.*
- AIR-PUMPS, 262.**
- Importance of the air-pump; remarks upon construction; observations in favour of those exhibited; Newman, exhibitor of the best air-pump, 262.*
- WATKINS.** Double-barrelled air-pump; Grove's principle, 262.
- KNIGHT AND SONS.** Air-pump on Siemen's patent, 262.
- VARLEY AND SON.** Air-pump; new construction; small double-barrel air-pump, 262.
- HEYWOOD.** Rotary table air-pump, 262.
- GOEHRTY.** Air-pump, 262.
- LADD.** Single-barrelled air-pump, 262.
- YEATES.** Double-acting air-pumps, 262.
- BRYAN.** Double-action air-pump, 262.
- BRITON.** Double-barrelled air-pump; form of construction objectionable, 263.
- DELEUIL.** Double glass-barrelled air-pump, 263.
- NISSEN.** Double-acting single-barrelled air-pump, 263.
- OPTICAL INSTRUMENTS, 263.**
- Importance of the telescope; a solid substance substituted by Wray for flint glass; optical glass in the Exhibition; Simms' object glasses; Chance's disc of glass; Daguerri; Doyère; Bertrand; Dubosey-Soleil, exhibitor of physical optics; microscopes; lighthouses, &c., 263.*
- TELESCOPES, 263.**
- VARLEY AND SON.** Apparatus for Gregorian telescopes; details of its construction; remarks upon the advantages of the Gregorian form of telescope; portable Gregorian telescope; construction, 263.
- ROSS.** Telescope; object-glass of English flint glass; tests to which it was subjected, 264.
- CALLAGHAN.** Telescopes for deer-stalking, 264.
- SALMON.** Telescopes for ship's use, 264.
- RICHARDSON.** Reflecting telescope, 264.
- BOYLE.** Reflecting telescope, 264.
- WRAY.** Refracting telescope; a solid substance substituted for flint glass; results of the test to which it was subjected, 264.
- WATKINS AND HILL.** Telescope, 264.
- MARRATT.** Achromatic telescope, 264.
- HARRIS AND SON.** Double-image telescope, 264.
- BURON.** Telescope; the object-glass of rock crystal; particulars necessary to attend to in working rock crystal; Huygens' formula; telescope supported upon M. Cauchois' stand; telescopes with terrestrial and celestial eye-pieces. M. Biot, 264.
- LEBRUN.** Achromatic telescope; introduction of a flint lens between the crown lens and joint focus; successful result of test, 264.
- KINZELBACH.** Dialectic telescope, 264.
- BUSCH.** Achromatic and other telescopes, 265.
- MICROSCOPES, 265.**
- Introductory remarks upon the large collection exhibited; importance of the microscope; application to geology;*

- services to the medical profession and to every class of society; instances of its powers of detecting adulteration both in grain and in textile fabrics; construction of the first object-glass by Tulley; Dr. Goring's opinion; desirable to trace the causes which have so conducted to its advance; date of the application of the achromatic object-glass to the compound microscope; Sellique's microscope; Amici; the late Mr. W. Tulley; Dr. Goring; successful combination of the lens; the result of Mr. Lister's researches; combination suggested by Mr. Lister, and constructed by Mr. Ross; new idea of Mr. Ross relative to the front lens; a new suggestion by Mr. Lister carried out by Mr. Ross; Poibell; Lealand; Ross; Smith and Beck; their successive exertions; valuable suggestions of Sir David Brewster; Wollaston's condenser; application to the microscope of the apparatus for the polarization of light; low price of the instruments exhibited by Messrs. Smith and Beck; combinations most suited for educational purposes; cautions concerning the extension of the angle of aperture; remarks upon combinations of high power and extremely extended angles of aperture; observations upon the qualities essentially requisite to the stand of a microscope, 265.
- ROSS. Microscopes; angular apertures of the object-glasses; quality of the object-glasses, 266.
- SMITH AND BECK. Microscope; observations upon the stand; lever motion of the stage the best yet applied; angular aperture of the object-glasses; well corrected for spherical aberration; new form of cabinet; two tables with revolving tops for the convenience of several observers, 266.
- VARLEY AND SON. Microscope; stage moved by parallel rods; microscopes for the reception of objects containing animalcules, aquatic plants, &c.; microscope for beginners; remarks upon Varley's lever stage, 266.
- KING. Microscope stand, with micrometers and goniometers; description; workmanship; mode of illumination, 266.
- PRITCHARD. Achromatic microscope; remarks upon the form of instrument, 267.
- LADD. Microscope with chain-and-spindle movements, 267.
- PILLSBURY. Microscope stand; its large size objectionable; small microscopes, 267.
- JACKSON. Plain and excavated slips of glass; sections of tubes, &c., 267.
- HUDSON. Microscopic objects, 267.
- HARR. Injected microscopic objects in illustration of the utility of the microscope, 267.
- POULTON. Microscopic objects; drawings in illustration, 267.
- STARK. Microscopic objects mounted in gutta-percha cells; slides for opaque objects, 267.
- SHARP. High power lenses, 267.
- SILANDHOLT. Sphero-anular condenser for the concentration of light; remarks upon the principle of the condenser, 267.
- FIELD AND SONS; ELLIOTT AND SONS; WATKINS AND HILL; ABRAHAM; GRIFFIN, exhibitors of microscopes, 267.
- Inferiority of the French object-glasses. Natchet's the best, but inferior to Ross, Smith and Beck; spherical aberration not corrected; a dissecting microscope exhibited by Natchet, 267.
- BERNARD. Microscopes, 267.
- CHEVALLIER. Microscopes, 267.
- BURON. Microscopes, 267.
- MEYER. Microscope; remarks upon its mechanical construction, and object-glasses, 267.
- HAZARD. Microscope; Huygenian eye-pieces, chromatic and spherical aberration not corrected, 267.
- PICK. Microscope, 267.
- Remarks upon the uses of the microscope; an important illustration of its utility afforded by Leonard, 267.
- List of subjects selected by LEONARD in illustration of the powers and utility of the microscope, 267.
- Remarks upon their execution, 268.
- TOPPING. Cases of microscopic objects; Mr. Topping's remarks upon the best medium for mounting; observations upon the method adopted by Mr. Topping, 268.
- BOURGONNE. Microscopic objects, 268.
- NOBERT. Tracings of parallel lines on glass; constitute admirable tests for object-glasses, and tend to confirm the undulating theory of light, 268.
- LINDY. Discs or minute copies on silver and steel, of various devices; remarks upon their minute size which render them almost invigible to the naked eye; details of the discs exhibited; remarks upon their utility, 268.
- OBJECT-GLASSES FOR TELESCOPES, 269.
- SIMMS. Achromatic object-glasses; remarks upon their colour; Mr. Simms' method of determining the corrections required for achromatism; specific gravities of the flint and crown glass manufactured by Chance and Co., 269.
- Remarks upon Mr. Simms' new invention and arrangements; a Council Medal awarded to Mr. Simms by the Jury, 269.
- GONNARD. Object-glass, 269.
- BURON. Achromatic glass, crown and flint-glass for which, made by late M. Guinard, with curves after Sir J. Herschel's method, to show stars of 11th magnitude, 269.
- READ. Solid eye-pieces; their construction; Sir David Brewster's achromatic sphere; Sir David Brewster's remarks upon achromatic eye-pieces; the inconvenience of the positive eye-piece now in use; examination of the eye-piece by Mr. Gluisher, 269.
- OPTICAL GLASS, 270.
- Examination of the disc of glass exhibited by Mr. Chance; gentlemen present at the examination of; description of tests to which it was subjected; satisfactory results, 270.
- MAES. Specimens of a new kind of glass; its compounds; suggestions, to manufacturers; prisms; discs of glass, 270.
- Remarks upon the achromatic union of the spectrum, 271.
- DAGUER. Discs of flint and crown glass; M. Daguer's process, 271.
- Lenses and prisms, 271.
- BEVERLY. Lenses of various forms; lenses ground on curves of different foci, 271.
- JAMIN. Prisms of crown glass; discs of flint glass; plane and convex reflectors, 271.
- BERTARD. Nicholl's prisms; crystals; variously cut prisms, 271.
- BURON. Various prisms, 271.
- LIGHTHOUSES, 271.
- CHANCE. Design for a lighthouse; improved method of reflection; arrangement of the prisms; system adopted by Fresnel; description of apparatus; colour of the glass, 271.
- WILKINS. Apparatus for a lighthouse, very similar to that of Chance; new adjustment of friction rollers, 272.
- PHYSICAL OPTICS, 272.
- DUBOSCQ-SOLEIL. Silbermann's heliostat; principle; saccharometer; mode of using it; Bravais's helioscope for showing halos, parhelicus, and meteorological phenomena; instructions for producing the several appearances; various instruments for physical investigation, 272.
- SPECTACLES AND OPERA-GLASSES, 272.
- Remarks upon the nature of the spectacles exhibited; regret at the undue amount of attention paid to the frames; contrast afforded by M. Henri in France, 272.
- ROWLEY. Spectacles; durability of framework, 273.
- WEAVER. Spectacles; hand-frame, 273.
- BRAITHWAITE. Ventilating eye-shades, 273.
- CHADBURN. Elastic steel-framed spectacles, 273.
- BAYLEY. Spectacles, 273.
- HYAMS. Glass for opera-glasses, 273.
- DIXEY. Spectacles; opera-glasses, 273.
- CLARK. Spectacles, 273.
- ELLIOTT AND SONS. Spectacles and opera-glasses, 273.
- HORNE, THORNTWHAITE, and WOOD. Smee's optometer, 273.
- BRADHAM. Spectacles, 273.
- CALLAGHAN. Steel spectacles, 273.
- SOLOMON. Eye-protectors, 273.
- WHITEHOUSE. Spectacles; a pair of sketching, 273.
- YEATES. Spectacles, 273.
- HENRI. Spectacles for rectifying obliquity of vision; spectacles for preserving the eyesight (*conserve les regards-rues*), 273.
- Remarks upon Mr. Henri's improvements, 273.

- POULLOT. Spectacles; metallic woven spectacles, 273.  
 LEBRUN. Cheap spectacles and opera-glasses, 273.  
 PRUDENT. Opera-glasses, 273.  
 BURON. Opera-glasses, 273.  
 BUSCH. Spectacles; opera-glasses, 273.  
 LATINIE. Spectacles, 273.  
 BAGEN. Spectacle glasses, 273.  
 PLACINOI. Spectacles, 273.  
 PICK. Spectacles, 273.
- DISSOLVING VIEWS APPARATUS, 273.**  
 ABRAHAM AND CO. Trinoptic prismatic lantern; description; dioptric prismatic lantern, 273.  
 CARTER AND WESTLEY. Phantasmagoria lanterns; lenses; subjects for dissolving views, 274.  
 HORNE, THORNTWHAITE, AND WOOD. Dissolving apparatus for the oxyhydrogen lime light; novelty of its arrangement described, 274.
- PHOTOGRAPHIC CAMERAS, 274.**  
*General remarks upon the camera; brief sketch of its advancement from the date of its discovery to the present time; spherical aberration carefully corrected by Mr. Ross; serious objections to the use of a white chamber as suggested by M. Blanquart; construction of the object-glasses exhibited, 274.*  
 ROSS. Cameras, with single and double achromatic object-glasses, 274.  
 HENNEMAN AND MALONE. A camera by Ross; description, 274.  
 KNIGHT AND SONS. Cameras; construction and adjustments, 274.  
 HORNE, THORNTWHAITE, AND WOOD. Camera; double achromatic object-glass; fine specimens of chemicals used in photography, 274.  
 CLAUDET. Cameras; multiplying camera; description, 274.  
 WILLIAMS. Portable photographic camera; a flexible cloth body instead of one of wood, 274.  
 VARLEY AND SON. Single reflecting cameras for enlarging or reducing copies, and for sketching from nature upon stone, 274.  
 ABRAHAM, ABRAHAM, AND CO. Portable sketching camera, 275.  
 PLACINOI. Camera, largest in the Exhibition; great defalcation of light; larger cameras have been constructed, 275.  
 SCHIENTZ. Camera; sides of the field very obscure, 275.  
 HARRISON. Cameras; double achromatic object-glasses, 275.  
 ALBERT. Camera; double achromatic object-glasses, 275.  
 ROUGET DE L'ISLE. Camera lucida for copying drawings; method of using it, 275.
- PHOTOGRAPHIC GLASS, 275.**  
 CHANCE AND CO. Discs of glass for daguerreotype and talbotype apparatus; its density and refractive power, 275.  
 BURON. Glasses for dissolving views, 275.
- PHOTOGRAPHY, 275.**  
*General remarks upon photography; not yet attained the rank of a science; its pursuit likely to elucidate principles at present unknown; photography yet in its infancy; the study of the prismatic spectrum, per se, recommended; regret that, as shown in the Exhibition, this study has been so little followed up; Mr. Claudet alone has done so; the method adopted by Mr. Ross in the construction of his cameras; the present exhibition of photographs will perhaps form an era from which to date many improvements; rapid advance of photography; an illustration of this rapidity; formation of daguerreotype establishments in London; amount of daily receipts on their first establishment; calotype process and its employment by Mr. Colten; injurious effects of the employment of the brush; Mr. Claudet's perfection of the processes; was the first to perceive the advantage of employing subsidiary adjuncts for backgrounds; pleasing results of Claudet's multiplying camera; mention of those gentlemen who have materially contributed to the advance of photography; M. Fizeau's new process of engraving and preserving the daguerrean image, 275.*  
*Sun-pictures; M. Bayard's celebrity; Henneman and Malone exhibitors of talbotypes; advantages attendant upon Mr. Talbot's process; M. Arago's opinion concerning the investigation of the photographic processes, 276.*
- DAGUERRETYPE PICTURES, 276.**  
 CLAUDET. Non-inverting portraits; distinguishing merits of Mr. Claudet's pictures, 276.  
 Difficulty of blending colour with photographic works; application of Claudet's focimeter, 276.  
 Claudet's dynamometer and focimeter; specimens illustrative of the different refrangible rays, 276.  
 KILBURN. Coloured daguerreotypes; individual merits specified, 276.  
 MAYALL. Uncoloured daguerreotypes; their characteristics; subjects selected for illustration; crayon daguerreotype, 276.  
 BEARD. Enamelled daguerreotypes, 277.  
 LAROCHE. Daguerreotypes, 277.  
 VOIGTLANDER. Coloured daguerreotypes, 277.  
 GRIFFITHS AND LE BEAU. Coloured daguerreotypes, 277.  
 PAINE. Photographic pictures to show the progress of the art, 277.  
 TYREE. Coloured daguerreotypes, 277.  
 CHADDOCK. Photographs copies of engravings, 277.  
*American daguerreotypes; their merits and character, 277.*  
*American excellence assisted by local influence, 277.*  
 LAWRENCE. Daguerreotype portraits; special mention of individual works, 277.  
 BRADY. Daguerreotype portraits; beauty of execution; remarks upon their backgrounds; several works particularized, 277.  
 WHIFFLE. Daguerreotype of the moon; a new era in astronomical representation, 277.  
 MAYALL. Subjects which compose his American collection; same characteristics as shown in his British collection; particular excellence specified, 277.  
 EVANS. Daguerreotype portraits; peculiar excellences, 277.  
 MEADE BROTHERS. Series of daguerreotype portraits; excellent arrangement of light and shade, 277.  
 PRATT, RICHMOND, AND CO. Daguerreotypes, 277.  
 WHITEHURST. Daguerreotypes of the Falls of Niagara, 277.  
 GAVITT. Daguerreotypes, 277.  
 ROOF. Daguerreotypes, 277.  
 HOGG. Daguerreotypes, 277.  
 LANGENHEIM. Talbotypes; hyalotypes, 277.  
 FONTAINE AND PORTER. Daguerreotype view of Cincinnati, 277.  
 HARRISON. Daguerreotypes, 277.  
*General Remarks upon the French daguerreotypes; their excellences, 277.*  
 THIERRI. Daguerreotype view of Lyons, 278.  
 MACOMBLE. Coloured daguerreotypes; their excellences more nearly allied to art than to science, 278.  
 SABATIER. Daguerreotype portrait of large size; remarks upon the excellence of its execution, 278.  
 PLACINOI. Daguerreotypes, 278.  
 GOVIN. Coloured daguerreotypes, 278.  
 KOHNKE. Daguerreotypes, 278.  
 VOGEL. Daguerreotypes, 278.  
 VON MINUTOLI. Daguerreotypes, 278.  
 TALBOTYPES, CALOTYPES, SUN-PICTURES, 278.  
 BUCKLE. Calotypes of great beauty: Mr. Buckle's observations upon the adjustment of the focus, &c.; Paper used by Mr. Buckle, 278.  
 ROSS AND THOMSON. Talbotypes; subjects of illustrations; remarks upon the diversity of tint; blue photograph and process by which obtained; albuminous process, 278.  
 HILL AND ADAMSON. Talbotype groups; striking effects of light and shade, 278.  
 HENNEMAN AND MALONE. Talbotypes on paper; subjects exhibited; their merits; excellence of the coloured portraits; specimens of the cyanotype and chrysotype of Sir J. Herschel; chromotype of Mr. Hunt; various talbotypes, 278.  
 COLLS. Sun-pictures on paper, 278.  
 HARMER. Calotype pictures, 278.  
 OWEN. Calotype pictures, landscape and wood scenery; advantages of Mr. Owen's glass spreader, 278.  
 COLLIE. Calotype pictures, 279.  
 RIPPINGHAM. Talbotypes; photographs from paper negatives, 279.  
 BINGHAM. Talbotype pictures, 279.  
 FIELD AND SON. Calotypes, 279.  
 MAITENS. Photographic proofs on glass and paper; special mention of works distinguished by peculiar excellence; in what that excellence consists; daguerreotype view of Paris, 279.

**BAYARD.** Sun-pictures, public buildings of Paris; calotype of Venus and Cupid, 279.  
**FLACHERON.** Sun-pictures; excellences; accurate representation of superficial texture, 279.  
**LE GRAY.** Sun-pictures, 279.  
**HENRI LE SEQU.** Calotypes; evils arising from negligence in the adjustment of the camera, 279.  
**EVERARD BLANQUART.** Talbotype pictures; a new process by which one negative proof is made to afford 200 or 300 impressions; its partial success, 279.  
**COUSIN.** Talbotypes, 279.  
**ALBERT.** Sun-pictures, 279.  
**CHEVALIER.** Photographic proofs, 279.  
**MAYER.** Talbotype miniatures; traces of the brush, 279.  
**PAUL PRITSCH.** Photographic pictures from nature, 279.  
*Closing remarks upon the collection of photographs; regret at the exclusive nature of the present application of photography; specification of those purposes to which it might be applied with effect and benefit; absence of all specimens of sculography, 279.*

**MAGNETS, 279.**

*Remarks upon the improvement of steel magnets; attention paid by Haarder to the permanent magnetic powers of cast-iron, 280.*  
*Dr. Sorensen's experiments upon the magnetic properties of cast-iron; Dr. Sorensen's results, 280.*  
*Mr. Haarder's experiment upon the magnetic properties of cast-iron, 280.*  
**LOGEMAN.** Permanent magnets; results of experiments, 280.  
**HENLEY.** Permanent magnets; results of experiments, 280.  
**SHAW AND SON.** Two magnets, of 9 lb. and 76 lb. weight respectively, 280.  
**HAARDER.** Cast-iron magnet; its construction; observations upon the relative powers of the magnetic plates when separated; permanent horse-shoe steel magnet; its weight and power, 280.  
**RENDALL.** Carbonized cast-iron magnet, 280.

**MAGNETICAL INSTRUMENTS, 280.**

**BROOKE.** Photographic apparatus for the self-distribution of the magnets; description of apparatus; chemical solutions for the preparation of the paper, 280.  
**WILTON.** Fox's dipping needles, 281.  
**PARKES AND SON.** Pocket compasses, 281.  
**GREEN.** Magnetic sun-dials; pocket compasses, 281.  
**PLATES.** Prismatic compass, 281.

**ELECTRICAL INSTRUMENTS, 281.**

*General remarks upon the necessity for an inexpensive instrument adapted for the observation of atmospheric electricity, 281.*  
*Application of steam-power to the production of electricity, 281.*  
**WESTMORLAND.** Gutta-percha electrical machine; description, 281.  
*Remarks upon the application of gutta-percha, 282.*  
**WATKINS AND HILL.** Electrical machine; construction; galvanometer; thermo-electrometer, 282.  
**DELEUIL.** Electrical machine for medical purposes, 282.  
**MEINIG.** Hydro-electric chain batteries, 282.  
**THERMO-ELECTRICITY.** *Introductory remarks on results of Lubbeck of Russia's discovery, in 1821, of electric currents generated by contact of two different metals in heated state, 282.*  
**SOSS.** Thermo-electric battery; construction, 282.  
**HOFFMANN AND FRIEDRICH.** An apparatus for showing the earth's magnetism, 282.

**APPLICATION OF ELECTRO-MAGNETISM TO THE MOVEMENT OF MACHINES, 282.**

*Remarks upon Professor Oersted's discovery, and the application of an active force produced without external influence, to the movement of machines, 282.*  
**JOULE.** Electro-magnet; estimate of magnetic force obtained; surface electro-magnet, 282.  
**HARRISON.** Electro-magnetic engine; principle of its action; construction, 282.  
**KNIGHT AND SON.** Electro-magnetic engine; simple in construction; electrical machine; its construction, 283.  
**WATKINS AND HILL.** Electro-magnetic engine; its principle and construction, 283.  
**ALLEN.** Electro-magnetic railway-train alarm, 283.

**CRESSWELL.** Electro-magnetic engine for the production of motion, 283.  
**FROMENT.** Electro-magnetic engine; its construction, 283.  
**BRETON.** Electro-medical apparatus, with double current, 283.  
**HARTH.** Electro-magnetic engine; plan of improved arrangement; detailed description of its action, 283.

**ELECTRIC TELEGRAPHS, 283.**

*INTRODUCTION; Four collection by Electric Telegraph Company; needle telegraph; rapid progress; Lessig's proposition in 1782; Lomond in 1787; Reizen; Saiva; Ronalds; Galvani; Volta; voltaic electricity, 283.*  
*Soemmering's points; Core's decompositions; Arago's and Faraday's discoveries; Pictet; Saxton; essentials of electric telegraph; generation of the force; different batteries; Botto's proposition, 284.*  
*The earth supplies electric force; means of setting the current in motion; magneto-electric machine; insulation of the force; Ronalds, Weber, Steinheil, Walker, 285.*  
*Use of gutta-percha; gutta-percha; insulation of street and tunnel wires; those under rivers, or harbours; first telegraph communication between England and France; different methods for submarine wire, 285.*

 HUGHES. Portable typograph; construction and method of using it, 311.  
 TOLLUTT. Machine for facilitating the writing of the blind, 311.  
 FORCAULT. Printing-machine for the blind; designer himself blind, 311.  
 THOMPSON. Invention for teaching the blind to draw and write; no explanation given to the Jury, 311.  
 GALL. Triangular alphabet for the blind; Gall's apparatus for teaching the blind to write, 311.  
 MANCHESI. Printing-machine for the blind, 311.
- MISCELLANEOUS, 311.  
 DUNIN. A piece of mechanism to illustrate the different proportions of the human figure; mechanical arrangements; dimensions of the figure; excellence of the workmanship; intended application; possible applications, 311.  
 LLOYD. Typhloelektor, or storm-pointer; description and use, 312.  
 CHALLIS. An instrument for calculating the sums of the errors of a transit instrument; construction; accuracy; addition required for different latitudes, 312.  
 BLUNT. Model of a portion of the moon's surface; Erastothenes, 312.  
 SPRATT. Lightning rods; metals used in their composition, 312.  
 NASMYTH. Map of the moon; enlarged representations of certain portions of the moon; their accuracy and good execution, 313.
- FISHER. Chart to illustrate the sun's declination at all seasons, and the coincident effect of light and heat upon various animal and vegetable productions, 313.  
 LEYSEL. Weber's electro-dynamometer for measuring the intensity of galvanic currents; general remarks upon the electro-dynamometer, 313.  
 ENGEL. Fresnel's wave surface, &c., 313.  
 WARD. Botanical cases, 314.  
 DE LA RUE. Iridescent films, 314.  
 VAN SCHENDEL. Anamorphosis, or illustrations of the laws of perspective, 314.  
 FISHER. "Mathematics simplified" by means of geometrically-drawn figures, 314.  
 PERIGAL. A demonstration of the theorem of the right-angled triangle by the transposition of parts; quadratic trisection of the square; diagrams of the retrogressive parabola; gyroscope, 314.  
 GERARD. Spherical trigonometer for the mechanical solution of trigonometrical problems, 315.  
 DEMARET. Conversion of vibrating into rotatory motion, 315.  
 YATES. Instrument for squaring the circle, 315.  
 ROBERTS. Synchrometer, 315.  
 COOKE. Closed case for plants, 315.  
 BATEMAN. Machine to illustrate the effects of centrifugal force, 315.  
 DARNELL. Apparatus for the detection of fire or robbery, 315.  
 SAUNDERS. Self-acting kaleidoscope, 315.  
 KNIGHT AND SOSS. Machine for cleaning and polishing daguerreotype plates; portable mercury-box; plate-holders; head-rests; glass and porcelain dishes for preparing sensitive papers, 315.  
 THOMSON. Autochronograph, 315.  
 DYER. Circular slate, divided into as many portions as there are days in the month; its use, 315.  
 ROPIER. Lawson's observing-chair, 315.  
 WATKINS AND HILL. Biot's apparatus for the polarization of liquids; polariscope; Attwood's machine; steam-engine indicator, 315.  
 NEWBERRY. Case of medals, 315.  
 RENDALL. Impressions of seals, 315.  
 WILLATTS. Registering thread-counter, 315.  
 HAWARD. Gauge for measuring thickness and weight, 315.  
 EDGE. Photometer, 315.  
 CHAMBERLAIN. Balloting machine, 315.  
 BAKER. Vacuum and steam gauges, 315.  
 BROWN. Patent power-engine to act as a water-meter, 315.  
 LAWRENCE. Screw-wrench, 316.  
 PLANT. Self-registering steam-boiler feeding apparatus, 316.  
 ROCHER. Tank apparatus, 316.  
 GREEN. Damp detectors; several angle-meters, 316.  
 MERRYWEATHER. Tempest prognosticator, 316.  
*General remarks upon the conclusion of the Report; probable good which will result from the Exhibition; no opportunity afforded for inquiry into the comparative importance of the different classes of instruments; each country characterized by some peculiar excellence; science will receive a fresh impulse; a means of self-education opened to the artisan; important conviction impressed on the mind; intimate union discernible between things apparently far separated; probable effects of the concentration of science; promotion of science one great result of the Exhibition, 316.*

## CLASS XA.

### REPORT ON MUSICAL INSTRUMENTS, &c.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

#### *Sub-Jury A for Musical Instruments.*

Sir H. R. BISHOP, *Chairman and Reporter*, 13 Cambridge Street, Hyde Park; Professor of Music at Oxford.  
 SIGISMUND THALBERG, *Deputy Chairman*, Austria; Professor of Music.  
 W. STERNDALE BENNETT, 15 Russell Place, Fitzroy Square; Professor at the Royal Academy of Music.  
 HECTOR BÉRIOT, France.  
 J. ROBERT BLACK, United States; Physician.  
 Chevalier NEUKOMM, Zollverein.  
 CAPTAIN POTTER, 9 Baker Street, Portman Square; Principal of Royal Academy of Music.  
 Dr. SCHATHAULT, Zollverein; Professor of Geology, Mining, and Metallurgy.  
 Sir GEORGE SMART, St. Anne's, Chertsey; Organist and Composer of the Chapel Royal.  
 HENRY WYLDE, 65 Westbourne Terrace; Doctor of Music and Professor at the Royal Academy of Music.

#### *Associates.*

Rev. W. CAZALET, Tenterden Street, Hanover Square; Superintendent of the Royal Academy of Music.  
 JAMES STEWART, 22 Brecknock Crescent, Camden Town; Pianoforte Manufacturer.  
 WILLIAM TILFORD, Dublin; Organ Builder.

THE JURY of Class XA, having concluded the examination of the various articles confided to their inspection, and having made their awards, have now, in accordance with the desire of the Royal Commission, to offer the result of their labours in an official form, which it is hoped may hereafter serve as a faithful and impartial register of the state of musical instruments, and their manufacture, in the year 1851.

When the very large number of articles (eighteen hundred and fifty-seven) in this Class, displayed in the Exhibition, is taken into consideration, the utter hopelessness of doing adequate justice to all exhibitors in such a Report as this is at once apparent. Nevertheless, the Jury are desirous to record the unfeigned satisfaction and pleasure which they have derived during their inspection, from becoming acquainted with some of the most beautiful specimens of musical instruments of all kinds ever manufactured; and it will be their consolation to know that the restriction which they are necessarily obliged to make in the length of their Report will be amply compensated by the increased intelligence of the musical public, who have not failed to visit those articles, and to reward them, in their own opinion, according to the merit displayed.

#### *Organs.*

In this department the Jury, after due deliberation, determined to award the Council Medal to the following makers:—

M. P. A. DUCROQUET, Paris, Messrs. HILL and SOX, and Mr. H. WILLIS, London, for their introduction of a fundamental pneumatic principle into the art of organ-building, by which means the great exertion hitherto required on the part of the performer on a large organ is no longer necessary, the labour being transferred to the bellows-blower; and thus the largest organs may now be built without exacting from the performer more physical strength than he is obliged to use in playing one of the smallest size and compass.

The following are the explanations of the various improvements illustrated in the organs which have been exhibited by the three above-mentioned builders, Messrs. HILL, WILLIS, and DUCROQUET.

The organ by Messrs. HILL and SOX has two manuals; compass C C to F (54 notes). Pedal organ C to E, 2½ octaves.

The great organ contains 10 stops.  
 The swell organ contains 5 stops.  
 The pedal organ contains 1 stop.

In this organ the following improvements have been introduced:—

1st. The "*Tuba Mirabilis*," a stop of great power and fulness of tone, the invention of Messrs. HILL. It is voiced on a much heavier pressure of wind than ordinary, namely, 11 inches, the ordinary pressure for church organs being from 2½ to 3 inches. This stop has a separate bellows and wind-chest, and has never been made by any other builder.

2nd. The "wind-trunks," for conveying the wind from the bellows to the wind-chest, are abolished, and hollow posts and framework substituted, thus effecting a great saving of room, and simplifying the general construction of the mechanism.

3rd. The application of a new valve to the great organ, the invention of Messrs. HILL, who first adapted it to the large pedal pipes in the York and Birmingham organs; it being found that such large pipes could not be supplied with sufficient wind by means of valves of the old construction, without increasing the resisting surface to such an extent as to render it impossible to open them by the pressure of the fingers, or even the feet of the performer.

The above-mentioned valve reduces the pressure, or rather resistance, to one-fourth of that presented by one on the old plan, and admits at the same time double the quantity of wind. This valve has now for the first time been adapted to the manuals, to which it insures equality as well as lightness of touch.

4th. The stops and sliders are shifted by means of the pneumatic apparatus; so that in changing the stops a key has merely to be pressed down, instead of drawing them off and on by means of draw-rods.

These keys act upon a set of valves which admit compressed air into a series of small bellows acting directly upon the sliders.

There is a small bellows at each end of a slider, one for pushing the stop on, and the other for taking it off. Upon one of the keys being pressed down, the valve is opened, and the bellows becoming suddenly inflated by the admission of the compressed air, a motive power is obtained sufficient to move the slider into its required position.

5th. The composition pedals are exceedingly simple in their construction, the performer having merely to move the keys above mentioned, which being very light are moved with great ease. The usual heavy iron-work is entirely done away with, and the action much simplified and condensed.

Mr. H. WILLIS's organ consists of three rows of keys, from C C to G (56 notes), and two octaves and a fifth of pedals, namely, from C C C to G (32 notes).

The pneumatic lever, as improved by the builder, is applied to the great and swell organs; the choir touch is lightened by pneumatic contrivance, counteracting the resistance offered by the pressure of the air, and a remarkably effective valve is applied to the 32 and 16 feet wood stops in the pedal organ, called the patent cylindrical pedal valve, though used for other purposes in the same instrument. The bellows supplying the swell organ are placed in the box itself, and give two pressures of air. The whole of the draw-stop movement is centred in a peculiar way—also patent.

The various organs have applied to them a novel and convenient movement for arranging the stops, called "The Patent Combination Movement."

The swell-box is constructed of 3-inch pine plank, with double front, upon the Venetian principle; the shutters of which (40 in number) are made of 2-inch pine, with leathered joints, &c.

The instrument will stand in a height of 27 feet, as at present arranged, and is 25 feet wide, by 22 feet 6 inches in depth; but it is capable of extensive alterations at a trifling expense, should they be necessary.

The following is a synopsis of its contents:—

|                         | Stops.  |
|-------------------------|---------|
| Great organ, C C to G   | - 20    |
| Swell organ, C C to G   | - 22    |
| Pedal organ, C C C to G | - 14    |
| Choir organ, C C to G   | - 14    |
| Couplers                | - - - 7 |

Observation 1.—The whole of the stop, extending throughout the compass of the various clavers, except the orchestral oboe, which, from its close resemblance to that instrument, is only of the same compass.

Observation 2.—The plan of placing the bellows in the abstract swell overcomes all the evils resulting from confinement of air by closing the front, thus the pipes remain in tune. The other advantages are obvious.

The following is a description of M. DUCROQUET's organ.

The instrument is composed of 20 stops; with two manuals and German pedals. Each manual comprises five octaves, from C C to C, and the pedals two octaves, from C C C to C. There are ten stops on the lower, or great organ manual.

Observation 1.—All the reed-stops on this manual are established on a separate wind-chest, and supplied with air at a greater pressure than that of the diapason stops.

Observation 2.—The reed-stops and the furniture can be withdrawn at pleasure by means of a pedal.

There are eight stops on the upper or swell manual.

Observation 1.—All the stops on this manual are inclosed in a swell.

Observation 2.—The upper manual can be coupled with the lower in three different ways, namely, in unison, octave above, and octave below. The couplers are brought into play by pedals, and in consequence of the application of the pneumatic lever, do not add in the slightest degree to the weight of the touch, whatever may be the number employed.

#### Pedal Stops.

|                      | Pipe |
|----------------------|------|
| Pedal pipes, 16 feet | -    |
| Ophicleide, 16 feet  | -    |

Observation.—The pedals act at pleasure on the bass of the great organ by a coupler.

The instrument is contained in a handsome oak case in the Gothic style. It measures 30 feet high, 12 feet broad, and 6 feet deep.

All the mechanical parts of this organ are constructed

of the best materials, and executed on the most approved principles. In addition to many late and important improvements, will be found peculiar dispositions, which have been adopted with a view of enabling it to compete, both in power and variety, with instruments constructed on a much larger scale.

Connoisseurs will, no doubt, be struck with the proportionally greater number of reed-stops introduced into M. DUCROQUET's organ, compared with organs of the same dimensions built either in England or Germany. The object has been to obtain a fuller orchestral effect: many of these stops, such as the oboe, cor-Anglais, and bassoon, being particularly adapted for the execution of solos; while the trumpet, clarion, and double-trumpet stops give unusual energy to the fortissimo passages.

It may, however, be necessary to observe, that the diapasons, which can alone give to the organ its essential character, have been by no means neglected. Of these there are two of 16 feet, and eight of 8 feet, five of which commence on the C C. It may be added, that among these stops are two of remarkable power and brilliancy, the harmonic flute and bell diapason; the latter of recent invention, never having yet been introduced in any other organ.

This instrument, built expressly for the Great Exhibition, for the special purpose of representing the actual state of organ-building in France, is equally suitable either for a church or a large concert-room.

A fourth Council Medal was also awarded by the Jury to MESSRS. GRAY AND DAVISON, London, who have invented a very ingenious and simple contrivance to combine the great organ with the swell organ, by means of a pedal, which acts with the utmost ease, and by which a very effective *forzando* may be produced; thus enlarging the musical field of the performer, and adding variety to the otherwise monotonous character of the most powerful and magnificent of all musical instruments.

MESSRS. GRAY AND DAVISON's organ contains their newly-invented stop, the *heranophon*, first introduced by them in the organ at St. Paul's Church, Wilton Place. It has also three manuals, and an independent pedal organ. There are—

| In the great organ |
|--------------------|
| " swell "          |
| " choir "          |
| " pedal "          |
| " couplers "       |

and six composition pedals.

Mr. J. C. BISHOP, London, and Mr. J. W. WALKER, London, have exhibited but few specimens of their organ-building. Such makers have not been passed over by the Jury without Honourable Mention, having ever been in the foremost rank of organ-builders.

A Prize Medal has been awarded by the Jury to JOHAN FRANZ SCHULZE, and SONS, Zollverein, for an organ, which possesses two manuals, and an independent pedal organ. There are—

| In the great organ | Stops. |
|--------------------|--------|
| " " " "            | 8      |

• MESSRS. SCHULZE's organ has blind prospect-pipes; the construction of the interior is therefore more simple. It requires no roller-boards, and is constructed with squares, which go in an oblique direction to the valves. In front, a vacant place for tuning is left, and the smaller stops may be placed in front, to the great advantage of the tone of the organ.

2ndly. It has a more powerful tone than others of larger dimensions; it has also several soft stops—the whole being constructed after the theory of Professor TÖFFER.

3rdly. It takes up less room than any other with the same number of stops, it weighs less, and requires less labour than organs of the same proportions.

4thly. It has claims for its comparative cheapness,

considering that it has more power and depth of tone than is usual in organs of the same size.

5thly. The trumpet 8' is a free reed-stop, it is tuned by screws, the crutch is fixed, while the plate and the tongue are moveable. The tone of this stop is more like that of a clarinet or bassoon, which has been attained by a novel covering of the body of the pipes.

6thly. The posanne (trombone) 16', is also a free reed-stop; it has, a strouger tone, and speaks quicker than a common reed-stop.

7thly. Messrs. SCHULZE's organ has also a *reserve* bellows, which assists materially the rapid speaking of the pipes, and which is of a peculiar importance, inasmuch as it provides a sure remedy for the unskilfulness of an organ-blower.

A Prize Medal has also been awarded to—

MESSRS. DUCCI, Florence, for a beautiful specimen of a chamber-organ, respecting which the following is an extract of the opinion of Signor Rossini:—

“Messrs. A. and M. Ducci, of Florence, have built an organ of a diminutive size, possessing the same tone as one eight times larger. Its chief peculiarity is the position of the lower notes, which are placed within the bench on which the player is seated. These lower notes are placed in one single pipe, which gives the lowest C with 16 feet, and the successive tones of the chromatic scale by means of eleven holes.” To obtain the tone of a large organ, the builders, Messrs. Ducci, have altered the form and disposition of the pipes, and invented a new species of mechanism. The instrument can be easily removed as it is, or it may be taken to pieces, packed up, and carried anywhere, just like a piano.

“The builders deserve great praise for this new instrument, which not only does honour to their ingenuity, but must expand the boundaries of art, particularly in the power it gives of uniting all the lower notes in one single pipe, which may thus lead to new mechanical improvements, and open sources of acoustic phenomena.”

Honourable Mention has been made of an harmonicon organ, invented by Lieut.-Colonel T. PERRONET THOMPSON, M.P., and built by T. J. F. ROBINSON, London.

MR. G. H. HOLDITCH has exhibited a small choir organ, the compass of which is from CC to F in alt. The stops are as follows: open diapason, as far as tenor C, 4 feet; stop diapason bass, celestina, principal, *diapason*.

The *diapason* stop has the effect of doubling every single stop throughout the instrument; the power, therefore, of the instrument is equivalent to one with twice the number of stops. This addition was invented by Mr. Holditch, who has applied it to church and chamber organs. The contrivance is very simple, and not liable to derangement. The organ possesses a pneumatic lever or valve, by which means the wind is made steady; also three composition pedals, with double actions to pull in and out the draw-stops. The pallets in the bellows are of peculiar structure, to prevent their casting or turning up from excess of heat or damp, which has been a great inconvenience in the formation of bellows hitherto.

#### *Pianofortes.*

The following remarks upon pianofortes have been contributed by Mr. Thalberg:—

“Having been invited to contribute towards a Report on the pianoforte, I proceed to comply, in as short a space as is consistent with the nature of the subject.

“It is necessary, in the first place, to notice the fact that music, though, perhaps, of all the fine arts, the first in the order of cultivation in every country, has been certainly the very slowest in its development. In all its sister arts we look for the finest productions of the past, and in some cases to very remote periods of European civilization, while the great productions in music belong, as it were, to the present time, and are nearly all included in the last seventy or eighty years, certainly in the last century. For ages, even amongst the most cultivated and polished people, music was confined almost wholly to melody; and its execution was bounded by the natural powers of the human voice, slightly and

artistically cultivated; and to instruments, most of which were exceedingly imperfect. But the pleasure from music, even then, was derived from a complication of separate effects; from the quality of the tone, from intonation or variation in the degrees of gravity and acuteness, from modulation, or the departure from and return to the principal key, from rhythm, or divisions into equal groups, from the modes of expression—*staccato* and *legato*, *forte* and *piano*, &c., and from the various movements appropriate to different feelings, from the solemn *adagio* to the merry *presto*. This complication of the elements of pleasure was increased by the employment of instruments in accompaniment to song, at first in unison with the voice, which gradually led to counterpoint, which in its turn immensely increased and varied the effects of music, caused the science to be far more studied, induced numerous experiments in musical acoustics, and gave a new and more elevated character to musical compositions. New instruments were invented, and old ones improved, accompaniments began to be composed to vary and heighten the effect of the melody, by using different figures of intonation, and orchestral effects were produced by appropriating different instruments to particular purposes. Then harmony, properly so called, began to be cultivated, or the flow of different melodies in harmonic agreement. At length came the great masters, as Handel, Bach, Haydn, Mozart, Beethoven, &c., who gave an entirely new, intellectual, and real artistic character to music, by employing in their compositions subjects appropriate to the character intended in the particular piece, and treating the different elements of musical pleasure in a methodical and artistic manner.

“These great composers thus elevated music to a level with its sister arts, and made the pleasure to be derived from it, like that from painting, complicated and refined, requiring a certain education in the hearer, as in the observer, to be able to understand and appreciate its higher productions, so that we may now include music with the other fine arts, in so far that the uncultivated taste feels only this or that element of pleasure, while the cultivated taste appreciates all the elements employed, and reaps the full enjoyment of the most beautiful productions of art.

“In this progress of the art composers found all the aid they desired for the composition of melody in the truth and flexibility of the voice and the violin; but for their orchestral and concerted pieces they could not keep in their studios bands of musicians. To meet this exigency they employed spinettes, clavichords, and harpsichords, and afterwards pianofortes, which, though feeble instruments of no great compass, answered this purpose so well as to become universally adopted by composers. This use of this class of instruments led to the peculiar capabilities of the pianoforte being thoroughly studied and appreciated; and the composers repaid their obligation to the instrument by writing for it many of the very finest productions in music, and by practising the execution of these productions to such an extent as to be able to bring them before the public with the greatest *éclat*. The importance which the instrument had thus gained led from time to time to its improvement and enlargement, and this again to still finer compositions being produced for it, and to the adaptation for the pianoforte of all the best orchestral compositions; so that the advance of the art, and the improvement of the piano, have had a mutual effect upon each other, until it is now beyond all question the first of musical instruments, both to the profession and to the cultivated classes of society.

“More than three centuries back there were in use two kinds of small instruments with key-boards; the Clavichordium, of a square shape, having strings of catgut, which were vibrated by bits of hard leather about a quarter of an inch long projecting from the side, and at the upper end of the jack, which was operated on immediately by the inner end of the key; and the Clavecin, of nearly the same form as the present grand piano, having strings, which were vibrated by plectrums of quill or hard leather. These limited instruments, with others of kindred forms, such as virginals, spinettes, and harp-

sichords, continued in use, with very slight improvements, for two hundred years, until the beginning of the last century, when, in 1716, Marius presented to the Academy of Sciences, at Paris, a Clavecin, whose strings were vibrated with hammers instead of plectrums. This was a very great step, wholly changing the quality and character of the tone of the instrument, and making it in reality a new and different one; in fact, the embryo piano. Two years after, Christoforo, at Florence, introduced some further improvements in the instrument, and produced what has generally been considered the first piano. But the new inventions, although immeasurably superior to their predecessors, had great difficulties to contend with, and were a half century in fighting their way into any considerable degree of favour. However, in 1760, Zumpe in England, and Silberman in Germany, had established small manufactories of the piano, and it was successfully competing with its more established rivals, as is sufficiently shown by its having been adopted and used by Haydn, who left sixty sonatas composed expressly for it. Gluck also adopted the piano; and we have seen the instrument on which he composed his *Armida* and other works, made for him by Johannes Pohlman in 1772. It is but 4½ feet in length, and 2 feet in width, with a small square sounding-board at the end, the wire of the strings being little more than threads, and the hammers consisting of a few plies of leather over the end of a horizontal jack working on a hinge. The instrument, compared with a fine piano of the present day, is utterly insignificant and useless; and it is difficult to conceive how it could have been used for the purposes it certainly served, till we reflect upon the importance to the composer of having at instant command any description of orchestral effect.

"About this time Sebastian Erard made the first pianos in France: in the following year Stodart patented in London a combination of the harpsichord and grand piano; and, in 1783, Broadwood took out a patent in relation to the piano. From this period pianoforte-makers rapidly increased in every part of Europe, especially in Germany, England, and France, showing how broad-spread became the estimation of the instrument. Since 1786, up to the present moment, hardly a year has passed without the appearance in England alone of patents for real or imaginary improvements, countless experiments being made, most of them totally empirical and unimportant, but some, especially in the last thirty years, truly scientific, resulting in the enlargement and improvement which we now find.

"In 1786, Gieh took out a patent for what is called the grasshopper action, which is still in use for square pianos, in the dampers of which improvements were patented in 1794 and 1798 by Southwell. In 1809, Sebastian Erard, to whose genius the pianoforte is so much indebted, patented the upward bearing of the strings, which was a very great and scientific improvement, now almost universally adopted. In 1819, Thom and Allen patented compensation metallic tubes, which were adopted by Stodart in the grand piano. These tubes, firmly fixed at one end, were made moveable in a slide at the other, to allow them to contract and expand with changes of temperature. They had not the slightest compensating effect as intended,\* but they were very effective for bracing, and certainly gave much greater strength to the frame. In 1821, Pierre Erard brought out his first repetition action, and in 1824 patented a complete system of metal-bracing for the grand piano, by bars firmly fixed at both ends to plates and abutments of metal, and employed a number of thicknesses of oak glued together in a mould to form the bent side, thus obtaining such increased strength of frame as to permit thicker wire to be used in stringing, from which he discarded brass altogether, and employed steel strings throughout the scale, which was followed, in 1827, by a new repetition action. Broadwood, Collard, Kirkman, Stewart, Wornum, and a few other

makers, have likewise contributed, in various degrees, at different times, to the progress of the instrument.

"During the first years of this century two systems chiefly prevailed with regard to the grand piano, the older one followed by the London makers, known as the English system, and the newer one in Germany, called the Vienna system. The difference was principally in the action, that of the English being the common grand action, the origin of which is unfortunately unknown; and that of Vienna a new action, invented, it is said, at Augsburg, by an organ-builder. The old grand action gave a more powerful blow and produced a fuller and finer tone, while the lightness of touch of the Vienna action afforded far greater facilities of expression, and caused it, therefore, to be adopted by most of the eminent pianists of the time. This is not at all to be wondered at, when we consider the immense importance of the action of the piano, in bringing out the elements of expression which are peculiar to the instrument. Between the mind of the player that conceives, and the string that expresses by its sound the conception, there is a double mechanical action; one belonging to the player in his fingers and wrists, the other to the piano in the parts which put the strings in motion. No two piano players touch the instrument alike—that is, no two players have the same mechanical action in their fingers, or produce the same tones; and the difference in the style and degrees of excellence of pianists is more owing to this than to any other cause. It is, therefore, self-evident, that that part of the piano which continues the action of the fingers, and completes the connexion between the mind of the player and the strings of the instrument, should have a delicacy and a power answering as near as possible to those of the hand of the player. Every difference in the action of the piano will give a corresponding difference in tone and expression; and hence this part of the instrument has at all times been justly considered of paramount importance, not only by the great professional pianists but by the highly-cultivated amateur player. Now, however, we have an action, the invention of the late Sebastian Erard, which gives a more powerful blow than the old grand action, and a far more rapid and delicate effect than the old Vienna action—thus combining the advantages of both systems.

"To give an idea of the degree of perfection attained at the present day in the construction of the piano, we will describe one of the grand pianos in the Exhibition.\* This instrument is 8½ feet in length, and 4½ feet in its greatest width; its frame is of enormous strength, compared with the instruments of former times, being heavily braced with wood below the strings, having a complete system of metallic bracing above the strings, firmly abutted, and consisting of longitudinal bars let into metal at each end, and having the curved side formed of a number of separate pieces glued together in a mould to insure durability and fixedness of form. Its sounding-board extends to the frame on all sides, except the space left for the action. The strings are made entirely of steel, and of wire so thick that the tension necessary to bring them to the proper pitch produces an aggregate strain equal to at least twelve tons weight, while they are passed through studs drilled into the metal-wrest plank, thus giving the strings an upbearing position, which prevents the slightest displacement of the point of contact by any force of the hammers; and the system of placing the strings on the instrument, determined by accurate acoustic experiments, causes them to be struck by the hammer at that precise nodal point which produces the freest and clearest tone. The compass is extended to seven octaves from A to A. The action of this piano is described by Dr. Lardner, in a work just published on mechanics, as 'a beautiful example of complex leverage in the mechanism which connects the key and hammer. In this instrument the object is to convey, from the point where the finger acts upon the key to that at which the hammer acts upon the string, all the delicacy of action of the finger; so that the piano may participate, to a certain extent, in that sensibility of touch which is

\* And yet for that very purpose they continue to be used by many celebrated makers up to the present time.—*Reporter*.

\* Mr. Erard's, in the British Department.

observable in the harp, and which is the consequence of the finger acting immediately on the string in that instrument without the intervention of any other mechanism.' The power of this instrument depending on the quantity of matter brought into vibration, the resonance, or the perfection of that vibration, depending on the correct proportions of its parts, and the accuracy of intonation depending on the nature of the bridging, the proportions of the strings, and their arrangement with regard to the blow of the hammer, are all most admirable; while the action depending on the peculiar mechanism employed far surpasses everything else of the kind, for it enables the player to communicate to the strings all that the finest-formed and most skilful hand can express, and becomes, as it were, a part of himself, reflecting every shade of his feelings, from the most powerful to the softest and most delicate sounds. This action is, indeed, so perfect, particularly in its power of delicate repetition, that if any note is missed in execution upon it, it is the fault of the player and not of the instrument. Many persons have a very meagre notion of the power of expression possessed by the pianoforte. The fact is, however, that it really possesses almost all those elements of expression which belong to any other instrument, and several which are peculiar to itself, from the circumstance of the various parts of music adapted to the instrument being brought out by the same hand and same feeling. An immense difference of volume of tone and of effect is produced by the manner of touching the keys and by the use of the pedals, especially upon an instrument of great power, fine quality of tone, and delicate mechanism in the action.

"The manufacture of the piano as a branch of trade is of very great importance, from the superior character of the principal workmen, and the great numbers employed, directly and indirectly, in connexion with it. In all the cities of the civilized world there are numerous makers of this instrument, with immense numbers of workmen; and in most secondary towns throughout Europe there are small makers; while the increase of the number of pianos, compared with the population is every year more rapid, a circumstance which is not observed in regard to other musical instruments. This is corroborated by the fact that some years ago pianoforte-music constituted only a very modest portion of a music-seller's stock; whereas now it fills more than three-quarters of his shelves, and makes his chief business. The number of teachers is something wonderful: many are reduced ladies, who find in this exercise of their acquirements the most available means of support. Every professional pianist has often had occasion to exercise his kindly and generous feelings in recommending and assisting accomplished women, whose helpless families would otherwise have been utterly destitute.

"The social importance of the piano is beyond all question far greater than that of any other instrument of music. One of the most marked changes in the habits of society, as civilization advances, is with respect to the character of its amusements. Formerly, nearly all such amusements were away from home and in public; now, with the more educated portion of society, the greater part is at home and within the family circle, music on the piano contributing the principal portion of it. In the more fashionable circles of cities, private concerts increase year by year, and in them the piano is the principal feature. Many a man, engaged in commercial and other active pursuits, finds the chief charm of his drawing-room in the intellectual enjoyment afforded by the piano.

"In many parts of Europe this instrument is the greatest solace of the studious and solitary.<sup>2</sup> Even steam and sailing-vessels for passengers on long voyages are now obliged, by the fixed habits of society, to be furnished with pianofortes, thus transferring to the ocean itself something of the character of home enjoyments.

"By the use of the piano many who never visit the opera or concerts become thoroughly acquainted with the choicest dramatic and orchestral compositions: this influence of the piano is not confined to them; but extends to all classes; and while considerable towns have often no orchestras, families possess the best possible substitute,

making them familiar with the finest compositions. The study of such compositions, and the application necessary for their proper execution, may be, and ought to be, made the means of greatly improving the general educational habits and tastes of piano students, and thus exerting an elevating influence, in addition to that refined and elegant pleasure which it directly dispenses."<sup>3</sup>

One hundred and seventy-eight instruments of this class have been exhibited, Great Britain contributing sixty-six of that number, according to the following Table:—

|                                 | Exhibitors. | Instruments. |
|---------------------------------|-------------|--------------|
| Great Britain — — —             | 38          | 66           |
| Canada (Colonial possessions) — | 1           | 1            |
| Nova Scotia ditto —             | 1           | 1            |
| France — — —                    | 21          | 45           |
| Zollverein — — —                | 18          | 26           |
| Belgium — — —                   | 6           | 16           |
| United States — — —             | 6           | 10           |
| Austria — — —                   | 6           | 6            |
| Switzerland — — —               | 3           | 3            |
| Denmark — — —                   | 1           | 2            |
| Russia — — —                    | 1           | 2            |

In the above department the three great European makers, MESSRS. BROADWOOD, COLLARD, and ERARD, have exhibited specimens of the most perfect and beautiful manufacture. And upon the subject of this highly-important and valuable instrument it is necessary to dwell with more than an ordinary force; though any attempt to analyze the entire structure of a pianoforte, comparing its former build with the present, would be here superfluous. We would, however, draw attention to the perfection at which this instrument has arrived, so that the public may review its past history, and acknowledge the debt of gratitude due to those makers who have so unceasingly worked for its improvement. And here it will be proper to state, that the Jury, appreciating the strong claims of the three makers, Messrs. Broadwood, Collard, and Erard, to public testimony, awarded them alike the Council Medal.<sup>†</sup>

Messrs. Longman and Co., of London, predecessors of Clementi and Collard, first introduced what is called the "hopper escapement." The invention of the damper, for checking the vibration of the strings, was due to a native of Ireland, and it was for a long time called the "Irish" damper.

About the year 1776, Becker, a German, undertook to apply the pianoforte mechanism to the harpsichord. In this task he was assisted by John Broadwood and Robert Stodart, at that time workmen in the employ of Burkhardt Tschudi, of Great Pulteney Street, London. After many experiments, the grand pianoforte mechanism was contrived by these three. It is, in all essential particulars, the same still used by Messrs. Broadwood and Messrs. Stodart, and is remarkable for its simplicity, efficiency, and durability. It may be emphatically termed the *direct action*.

Messrs. Broadwood alone, from 1780 to 1851, have made with this mechanism (slightly modified from time to time) upwards of eighteen thousand full-sized grand pianofortes, besides fifteen hundred pianofortes of small dimensions.

The earliest notice of a pianoforte in their books occurs in 1771 of a *grand* pianoforte in 1781. Clementi was the first to bring the grand pianoforte into notice as an effective *concert* instrument. He played on one by Broadwood in the Pantheon, Oxford Street, in 1782.

The total number of pianofortes of all kinds made by Messrs. Broadwood from 1771 to 1851 is one hundred and three thousand seven hundred and fifty, and of these, sixty thousand three hundred and eighty-two have been made from 1824 to 1850—an average of about two thousand two hundred and thirty-six *per annum* for that period. The number of persons employed in their manufactory, at the taking of the census in 1851, was five

\* End of Mr. Thalberg's remarks upon pianofortes.

† This award was only confirmed by the Council of Chairmen in Mr. Erard's case.

hundred and seventy-three. Besides these there are numerous persons working at home for the same firm.

It is clear that for many years the pianoforte was inferior to the harpsichord; for when, in 1765, Burkhardt Tschudi presented an instrument to the King of Prussia, it was a harpsichord with two rows of keys. This instrument is still at Potsdam. The strings of the harpsichord being very *thin*, the wooden framing of the case sufficed to bear the tension. As soon as the strings of the pianoforte were increased in thickness it became necessary to strengthen the cases, and *steel arches*, therefore, were introduced between the strings. So early as 1808, Messrs. Broadwood applied horizontal steel bars over the strings. The number of these bars varied from two to seven.

Messrs. Stodart, in 1820, patented a system of bracing by means of *hollow* metal tension bars applied over the strings, combined with a suspension bar over the wrest-plank.

In 1824, Mr. Erard patented a somewhat different system of horizontal metal bracing.

In 1827, Messrs. Broadwood patented a third system of metal bracing for the grand pianoforte. It was a combination of the metal bars already adopted by them, with the metal string-plate which had by them been first applied to the square pianoforte in 1822. The four pianofortes which have been exhibited by this firm, may be described, as to externals, as follows:—

1. A grand pianoforte in the *Narr*, ebony case richly carved and gilt; the top, ebony inlaid with satin-wood; above each of the three legs is a medallion, carved and gilt, having busts of Handel, Mozart, and Beethoven. The design by E. M. Barry, Esq. 2. A grand pianoforte in Amboyna-wood case, with carving. 3. A grand pianoforte in plain Amboyna-wood. 4. A grand pianoforte in Italian walnut-wood case.

Of these four seven-octaves, C to G, grand pianofortes, two have each three straight tension-bars parallel to and over the strings. Of the other two, one has *one* parallel bar and *one* long oblique bar: the other has *one* parallel bar and two oblique bars. The scale of this latter instrument may be considered as a triangle of unequal sides, divided by these three bars into *four* triangles. This instrument is the most sonorous of the four. In all the four pianofortes any bending of the wrest-planks is obviated by the application of a metal transverse suspension bar, placed over and nearly in a line with the studs. The peculiar application of this suspension-bar is considered as an essential improvement. The tension-bars are also new, and entirely peculiar to these instruments, being constructed with flanges on each side to prevent twisting. A section of these bars transversely would present the figure of a cross +. The strain of the strings on these instruments is immense, notwithstanding which they stand in tune far better than those constructed with the ordinary bracing. In the four pianofortes exhibited, the following improvements are illustrated, and are claimed by Messrs. Broadwood as being entirely their own:—

- 1st. A newly-revised harmonic scale of strings.
- 2nd. A peculiar method of fixing the sounding-board.
- 3rd. The transverse metal suspension-bar. (It supports the wrest-plank, enabling the maker to dispense with several direct tension-bars, which are just so many impediments to free vibration.)
- 4th. The construction of the tension-bars. These are constructed in such a manner as to combine the maximum of *strength* with the minimum of *weight*.
- 5th. The fixing these tension-bars in the string-plate by means of wedges, thus insuring equal tension.
- 6th. The diagonal tension-bars. These abut against the strongest angle of the wrest-plank and *bass* side. They meet effectually what is commonly termed the "side-swing" of the string-plate, and they enable the maker to do with a single direct tension-bar.

The whole of the above-named six novelties of invention are dated by Messrs. Broadwood in the year 1847.

It is by the combination of most of the improvements just mentioned that this firm has attained, in their pianofortes, not only more sonorous tones, but a greater perfection of the quality of tone. Again, there can be no doubt but that simplification of bracing, in the construction of

pianofortes, will *eventually* enable the public to obtain first-rate instruments at a comparatively moderate price. And it is proper to record that, up to this time, the aim of most makers has been to introduce as much iron or other metal bracing as safety to the quality of tone would bear, and that Messrs. Broadwood are now the first to retrace such steps, learning from experience that tension-bars are but make-shifts, and that it is probable that the best mode of constructing a pianoforte would be to strengthen the case by other means, superseding the tension-bars altogether.

It should also be noticed that the action used by Messrs. Broadwood in their pianofortes is of the most simple and effective kind, and that its very simplicity is a guarantee for its durability.

Mr. P. ERARD has exhibited a variety of pianofortes in the British and French Departments. In these pianofortes considerable improvements have been made with regard to the mechanical part of the action, which has become one of the most perfect existing,—answering the purposes of the most intricate manual dexterity of the performers of modern times. This maker combines with his improved mechanical action a peculiar structure of the body of the pianoforte, by which a highly-successful result is attained.

Various patented improvements in the mechanism, &c., of pianofortes, are displayed in the instruments exhibited by Mr. Erard, of which the following is a description:—

BRITISH DEPARTMENT.—1. Extra grand pianoforte, in walnut-wood, with carvings gilt; seven octaves, A to A; with Erard's patent repetition action (1821); patent up-bearing (1809); complete system of metallic bracing (1825); and other improvements (1850). See description in remarks.—2. Extra grand piano (1850), with pedal keys.—3. Extra grand piano, with new patent metal wrest-plank (1850).—4. A short grand, six and three-quarters octaves, new scale, C to A; in a rose-wood case, with nullings.—5. Extra grand walnut, oblique, with carvings in the Elizabethan style; seven octaves, A to A; braced with four metallic bars (1850). Action patented (1840).—6. The same, in ebony, inlaid with silver (repetition action); also braced with four metallic bars (1850).—7. Satin-wood; six and three-quarters; oblique. Patent of 1840.—8. A new patent frame, with new screws, tuning apparatus for upright pianofortes; the same having been specified in the patent for horizontal pianofortes.

FRENCH DEPARTMENT.—1. Extra grand pianoforte, in tulip-wood case, inlaid with silver bands, tortoiseshell, and brass, elaborately engraved, supported by six caryatides, in the most rich and elegant style; seven octaves, A to A. Patents of 1809, 1821, 1825, and 1850.—2. Extra grand pianoforte in rosewood, with or-molu ornaments; seven octaves, A to A.—3. Short, or semi-grand, with repetition action (1809); six and three-quarters octaves, C to A.—4. Grand square pianoforte, of a new form, with repetition action (1821), metal bracing (1825), upward bearing (1809), on the principle of Erard's grand; six and three-quarters octaves, C to A.—5. Grand oblique of seven octaves, braced with four metallic bars. Patents of 1840 and 1850.—6. Oblique rosewood, with or-molu nullings; six and three-quarters octaves, C to A. Patent of 1840.

MESSRS. COLLARD AND COLLARD have exhibited several pianofortes, of which the following is a description:—

1. A grand pianoforte, in a case of British mottled oak, with carved and gilt ornaments, in the style of Louis XV.; seven octaves, A to A.—2. A grand pianoforte in rosewood case, with carved cabriole truss supporters; seven octaves, A to A.—3. A square semi-grand pianoforte, in walnut-wood; six and three-quarters octaves.—4. A grand cabinet pianoforte, in a case of British oak, of novel design; six and three-quarters octaves.—5. Two microchordous, or semi-cottage pianofortes, in pine and rosewood cases; six and three-quarters octaves. Exhibited as specimens of superior instruments of their class, at very low prices.

In the above-named instruments the following patented improvements are illustrated:—

1. In the mode of stringing pianofortes, by passing the wire round a single pin, in all classes of pianofortes, thus superseding the use of the noose or eye, before in general use. Patent of 1827. This mode of stringing has become almost universal since the expiration of the patent.

2. Applying a check to the under-hammer, to prevent the rebound of the hammer against the string. Patent of 1829.

3. A new construction of the action in horizontal grand and square pianofortes, the escapement being placed upon the key, and coming into contact with a lever or crank, and thus regulating the rise and fall of the hammer. Patent of 1835.

4. The introduction of a new class of square pianoforte, entitled "the square semi-grand pianoforte;" in which a closer approximation to the peculiarities of the horizontal grand pianoforte was attained. Patent of 1838.

5. The introduction of the traversing escapement fixed upon the hammer-rail, thereby admitting of a firmer blow and greater resistance, as also the introduction of a repetition movement. Patent of 1841.

6. The application of the repetition movement to square and to vertical, or upright pianofortes. Patent of 1843.

7. A new design for the shape of a square pianoforte, entitled "the Symmetrical Grand Square," by which greater beauty of form was secured, the key-board being placed in the centre of the instrument. Registered in 1847.

Several other makers of the pianoforte have contributed to the success of the musical department of the Exhibition, to whom the Jury have awarded the Prize Medal: their names will appear in the Award List.

#### *Harps.*

Mr. P. ERARD has exhibited eleven harps in the British Department, and two in the French Department.

In the manufacture of harps several highly-successful and important improvements have been made by this house, particularly in the invention of the *double-action* harp; and there cannot be a doubt that, from the perfection of their mechanism and the excellent quality of their tone, their harps are unsurpassed by any other maker.

In awarding the Council Medal to Mr. P. Erard, with reference to his pianofortes, the Jury took into consideration the great merits of his harps, and have, therefore, included them in that award.

In this class of instruments Honourable Mention has been made of Messrs. B. JONES, for an improved triple-strung Welsh harp, United Kingdom; and DOMÉNY (France).

A beautiful and very ingenious specimen of the *harp guitar* (called a "guitarra harpa") has also been exhibited, and for which the Jury have awarded a Prize Medal to the inventor, J. GALLEGOS (Spain).

#### *Bow Instruments.*

In this department the Jury have awarded the Council Medal to Mons. J. B. VUILLAUME, of Paris, for the excellence of his violins and other bow instruments, and for his invention of the *Octobasse*.

M. Vuillaume is entitled to pre-eminent rank among those modern manufacturers who have more or less contributed to restore that peculiar art, which, at the commencement of the last century, had been brought to such perfection by the far-famed *Italian* makers of violins and instruments of that class, but which for a long time appeared to have been entirely lost. His instruments, and, it must not be forgotten, those of other modern makers, will bear comparison with some of the best productions of the great *Italian* masters, whether as to perfection of form or quality of tone; while, from their moderate cost, compared with the enormous prices, to which, from time to time, those of the ancient makers have risen, a very essential service has been rendered to the musical art.

Some highly-meritorious specimens of violins, violas, violoncellos, and double basses, have also been exhibited, particularly those by the following makers, to whom the Jury have awarded Prize Medals:—

United Kingdom.—Messrs. A. BETTS, S. A. FORSTER, PURDY, and FENDT.

United States.—G. GEMUNDER.

France.—BERNARDINI, sen.

Honourable mention has likewise been made of Messrs. J. K. HEAPS, United Kingdom; P. HIGGINS, Canada; J. TONNA, Malta; G. and A. KLEMM, Zollverein.

#### *Brass Instruments.*

The following remarks have been contributed by a Juror:—

"Among the musical instruments exhibited in the Exhibition, the number of brass instruments, 'instruments de cuivre,' is considerable.

"England, France, and the German States are the countries which have contributed largely and nearly exclusively; whilst America, Hamburgh, Canada, Denmark, and even Russia, swelling the list of instruments with fixed tones, such as pianofortes and organs—or instruments of wood, such as flutes and clarionets, &c.,—do not appear as manufacturers of brass instruments.

"As in all other instruments of music (machines producing isochronous vibrations of not fewer than 16, or more than 8,192, vibrations in a second), so in wind instruments three things are distinguishable, viz., the 'striking body,' the 'regulating medium,' and the 'sounding-mass.' In the pianoforte the 'hammer' is the sounding-body, the string the 'regulating medium,' and the 'sounding-board,' the 'resonant-mass.' In wind instruments, the 'air-blast' from the mouth, taking the place of the hammer on the string, is the sounding body, which acts on the air in the tube of the instrument; the latter is the regulating medium, controlling the number of vibrations, and the pitch of the sound, and this air acting by friction on the body of the instrument, the 'resonant-mass,' brings the whole into resonance, and a musical sound is produced.

"That instruments of this class might, in the early ages of the world, have been more perfect than others seems likely; for our forefathers well understood, for acoustical purposes, the use and power of the lungs to act on the 'sounding-body' of wind instruments. Great mechanical ingenuity was not required in the construction of the latter, nature having endowed them with a power which no human mechanical contrivance has ever equalled, or is ever likely to equal; for though in machines composed of wind instruments or pipes, such as organs, 'the bellows' (which are artificial lungs) are employed and preferred; from the great bulk of agitated air required, it is at the expense of nearly all force, sharpness, and power of modulation of tone, rendering the organ and its imitations, in spite of the eucumiums of the unlearned in musical sounds, one of the least perfect of all musical instruments.

"That the organ is the king of instruments, or best collection of wind-instruments, in itself more perfect than any other, and capable of producing most effect on the mind of the hearer, is an illusion which may be referred to the circumstance that it is generally placed in a building such as a cathedral, whose reverberations and 'resonant mass' produce most of the effect attributed to the organ itself; an illusion which would be destroyed, were the organ removed to a different kind of edifice, for instance, to the Crystal Palace, and if a number of wind-instruments acted upon by the 'human lungs,' whose voluminous expansion of sound were equal to that of the organ, to take its place in the cathedral.

"The injury to the effect of the organ, by change of situation, may be appreciated by hearing those already in the Crystal Palace; and yet two of them are very fine specimens, one by Messrs. GRAY and DAVISON, the other by WILLIS.

"Listen to their tones; where is the grandeur attributed to the organ in the cathedral?—it is not discovered in the 'Palace of Glass.' To counterbalance this loss, where is its power of expression and power of modulation of tone combined with sonorousness?—it has neither. These qualities are not possessed by instruments making use of 'artificial lungs,' to act on the sounding mass. So, then, deprived of a building, to whose column of air it acts as the sounding body to bring it into resonance, as a small pipe is used to bring the large diapason into resonance, it is eclipsed by an insignificant-looking 'Sax or euphonio

horn,' blown by the 'human lungs,' and capable of giving expression to music; and to induce even the multitude to listen to the organ (who, perhaps, respect it from its early association with our religious services, and the effect produced by it on their minds in the cathedral), it has been found necessary to get one of these small wind-instruments to mingle its more expressive and exciting sounds. I allude to the combined performance of the euphonic horn and organ, which has been so often heard in the Crystal Palace.\*

"The modern makers of wind-instruments having the 'air-blast' as a sounding body, and the mechanism for acting upon it perfect, have turned their attention to the improvement of the wind-course as the 'regulating medium,' particularly in valved instruments: they have endeavoured to avoid the angles caused in the tube by the action of the piston. The improvement of the form and quality of the 'sounding mass' has also occupied their attention.

"As the examples are few of sound produced by undulation of air without resonance (perhaps one is thunder, which may be called a purely aerial sound, but which sets in motion a greater bulk of air than all the machines for producing sound in the world put together), and acknowledging that the resonant mass is a distinguishable feature in musical instruments; so, taking the well-known instrument, the pianoforte, as an example, and regarding the use of the sounding-board as 'resonant mass' in that instrument, we shall be able to judge, by analogy, how justly the attention of wind-instrument makers has been turned to the resonant mass, case, or sounding-board, of their instruments. The effect of a string set into vibration by the sounding body in the 'framework' of a pianoforte is not appreciable, although its vibrations are within the prescribed limits; but when set vibrating in connection with the sounding-board, or 'resonant mass,' it brings the whole into resonance, completely controlled by the 'regulating medium,' (the string), and the result is a voluminous expansion of the tone. The greater the resonant power of the sounding-board, the greater is the expansion of the tone. So with wind instruments, the greater the resonant power of the material of which the instrument is made, the more powerful is its volume of tone; but no indistinctness is produced on these instruments, by carrying this expansion of sound to its greatest attainable point, from the character of the regulating medium, and the comparative slowness with which notes are required to be produced. But, in the pianoforte, if this expansion of sound is carried too far, much indistinctness is the result.

"The use of metal as the 'resonant mass' of all wind instruments, besides those usually known as brass metal instruments, is becoming very general; thus we have the flute, *par excellence*, of Mr. Boehm: the clarinet, *par excellence*, of Mr. Pask; and the bassoon, *par excellence*, of Mr. Sax, made of metal.†

"Brass is the material which is most generally preferred for wind instruments, though to the fancy of an American exhibitor we are indebted for a flute made of 'galvanized India-rubber.'

"On hearing and examining this class of musical instruments, and comparing those made on the old principle of construction with those possessing the improvements effected of late years, both in their acoustical proportions and in their mechanism, the superiority of tone and facility of performing on these (many of them unwieldy) instruments is very striking. This facility is acquired by the application of valves to all kinds of brass wind instruments, enabling the performer of moderate ability to

produce on his instrument every note of the 'gamut' or 'scale' with the greatest rapidity; if not as pure in tone and vibratory as the harmonic notes, yet with such justness of intonation and freedom as can rarely be produced on the harmonic instrument (or instrument without valves) even in the hands of a superior performer. The inventor of these valves is unknown, but their introduction is due to the munificence of the Emperor of Russia, who about 24 years ago presented a complete set of brass instruments with valves, to the band of the Second Life Guards.

"Mons. Perrinet, a native of France, seems to deserve the credit, amongst the instrument-makers, of having, about twelve years ago, first materially improved the construction of valved instruments; and the English and French exhibitors have been very successful in carrying these improvements still further: thus the equilateral valves invented by Mr. Oates, a surgeon of Lichfield, shows the improvement which he has effected in the wind-course of brass instruments, avoiding many of the numerous angles caused in the wind-course by the action of the piston.

"The instruments exhibited by Mr. KOEHLER, of Henrietta Street, Covent Garden, made on the plan invented by Mr. Shaw, of Nottingham, called the 'patent lever action,' are of a decidedly superior character: and the ingenious contrivance for obtaining a free wind-course in valved instruments is highly successful.

"The instruments of Mr. PASK, 141 Strand, are all of the first order; they have great sonorousness, power, and facility of execution.

"Those by the French exhibitors, viz., by Messrs. ANST. COURTOIS, BESSON, AUG. COURTOIS, and GAUTHROT, and those by MAILLON, of Belgium, possess in every respect the qualities which in these instruments are required, some having greater fulness of tone than others, but all are constructed on the best-known acoustical principles, of very superior manufacture and finished mechanism.

"The instruments exhibited by M. SAX, of Paris, show great advancement; for not only do many of them, such as French-horns, trumpets, and trombones possess additional power, sharpness, and impressiveness, obtained in a great measure from their remodelled proportions (proving that it is not the quality of the metal brought into vibration by the air-blast which influences to any great extent the quality of the tone produced, and that successful results have ensued from an improved modification of form), but many of them, viz., the so-called 'Sax-horns,' possess a quality and richness of tone unheard until the introduction of these instruments by M. Sax.

"The instruments exhibited by the German manufacturers, though not so perfect as those of the French and English manufacturers, have some excellent qualities; and the euphonic horn, invented by Herr Sommer, is an instrument of great power, as well as sweetness of tone.

"Two ingenious contrivances for changing the keys of brass instruments without the use of crooks, are exhibited by M<sup>r</sup>. GAUTHROT, of Paris, and Mr. J. CALLCOTT, of London, the former making use of a screw, the other a 'radius-tube,' for lengthening or shortening the wind-course of the instrument.

"Judging from the number of makers, it may be supposed that the demand for this class of instruments is considerable. There are upwards of thirty exhibitors of brass instruments, and the number of instruments contributed by M. Sax, amounts to nearly fifty. It is well known that the demand has of late years increased amazingly, which may be attributed to the ease with which command is now obtained over these instruments by the use of valves, the less force required for the air-blast consequent on the better form of the instrument, and their present comparative cheapness. But it is in this point, viz., cheapness, that our English makers are eclipsed. That their brass instruments are equal to the French and superior to the German cannot be disputed, but they must be bought at a price often fifty per cent. dearer than those of the French or German makers."

\* That the Crystal Palace was very unfavourable to the effect of even the largest organs exhibited, does not admit of a doubt; but I cannot agree with the contributor's remarks on organs in general, nor do I believe that it was "found necessary" to employ either a "Sax or euphonic horn" to "induce the multitude to listen" to any one of the organs in the Exhibition.—*Reporter*.

† The invention of the bassoon exhibited by Mr. Sax is claimed by Mr. Cornelius Ward, of London, to whom a patent for it has been granted in France.—*Reporter*.

## WIND INSTRUMENTS.—WOOD AND METAL.

*For Orchestras and Military Bands.*

In this department the Jury awarded the Council Medal to—

M. ADOLPHE SAX (Paris), for his invention of several new classes of wind-instruments, in wood and metal; and to T. BOEHM (Munich), for his important scientific improvements of the *flute*, and the successful application of his principles to other wind instruments.

The following remarks have been contributed by a Juror:—

"Among the inventors of musical instruments, the highest distinction is due to the merits of M. ADOLPHE SAX, whether considered with regard to the variety, excellence, or the utility of his inventions. His creation of the entire class of Sax-horns, and Sax-trumpets, has produced the most satisfactory results, in the total revolution of military music. Both in the theatre and the concert-room, the two extremities of this vast instrumental scale can be introduced with important advantages. His *Sax-horns* (double-bass in E flat, and B flat) have left ophicleides very far in arrear; and his small treble Sax-horn, in B flat, is the only brass instrument known that can reach with certainty and just intonation the notes of the upper octave of the flute. His cornets-à-pistons are the best we are acquainted with.

"M. Sax has also created the class of Saxophones, brass instruments with a simple reed, similar to the clarinet. The effect of these new instruments possesses a charm equal to the originality of their tone, and they carry to the highest degree of perfection '*la voix expressive de l'orchestre*.'

"It must be conceded, that his bass and double-bass clarionets, in wood and metal, are inventions of inestimable value. Besides these, he has added a semitone to the lower register of the ordinary clarionets, and by a new *key*, has rendered it possible for the performer to take the upper notes at once with the greatest ease.

"M. Sax has also contrived to fill up the gap which existed between the lower E and the lowest B flat of the tenor trombone, by very simple means; and his brass *bassoon*, with a new system of holes and keys, is very perfect.\* He has likewise invented a contrivance for brass instruments with mechanical cylinders, as simple as it is ingenious, by means of which the sound is *continued* upon those instruments, as upon the violin, sliding-trombone, and with the voice, in passing from one note to another through all the *enharmonic intervals*.

"Lastly, M. Sax has adapted to the bugle-horns of infantry bands a set of portable tubes, which, on being adjusted to simple bugles, transforms them into cylinder bugles of various keys; thereby changing the monotonous character of the simple bugle, by giving it the means of producing all the intervals of the musical scale.

"M. BOEHM's inventions may be described as follows:—Firstly, he has brought the acoustical proportions of tubes and the finger holes of wind instruments into correct numbers and measurement, by which means flutes, oboes, clarionets, bassoons, &c., can be theoretically constructed. Secondly, he has invented a mechanism for the keys which gives facility and precision to the execution, and by which the former difficulty of reaching or stopping the holes at great distances, or of large sizes, is now surmounted. As by these means the holes can be made correct in size and position, M. Boehm has acquired not only a perfection in tone and tuning never before attained, but also a great facility in playing in those keys which were hitherto difficult and defective in sonorousness or intonation."

It is proper to notice, that among the brass instruments exhibited by Mr. Köhler, was an improved Chromatic Trumpet, invented by Mr. T. HARPER, sen., and which has been acknowledged by competent judges to be the best instrument of its kind.

\* It has been already stated that the invention of the bassoon exhibited by M. Sax is claimed by Mr. Cornelius Ward, of London.—*Reporter*.

It should also be mentioned, that several improvements are illustrated in Mr. J. CLINTON's Flute, exhibited by Mr. H. POTTER, in which the facilities of other modern flutes, and the ordinary system of fingering are combined, and their defective parts avoided. In this instrument the tone and tuning are rendered equal by the same means that M. Boehm has adopted, namely, an equality of size and distance in the holes. It has likewise claims to consideration for comparative cheapness, the mechanism being so simple, that its price does not exceed that of the old eight-keyed flute.

The Jury have awarded the Prize Medal to various makers of wind instruments whose names will appear in the Award List.

*Harmoniums, &c.*

In the class of musical instruments, including Melodians, Seraphines, Panorgues, Aeolians, &c., Messrs. WHEATSTONE and Co., of London, have exhibited a very ingenious and effective one, called the Portable Harmonium, of which the following is a description.

It has a compass of five octaves, commencing from the lowest C on the violoncello, the key-board being on the same extent and scale as the larger harmoniums. It can be instantaneously folded up, so as to occupy less than half its height, and half its length.

This instrument is quite original in nearly all its mechanical parts. It is peculiarly constructed for producing expression, and may either be used by itself for the performance of music written for the organ or harmonium, or for taking violin, flute, or violoncello solos or parts—its capabilities of expression giving it great advantages in imitating these instruments. It may be used in front of the key-board of a pianoforte; thus enabling the performer to give a hand to each instrument, and by this means to produce a variety of effects.

The Jury have awarded the Prize Medal to Messrs. WHEATSTONE and Co., also to M. JAULIN, of France, for instruments of this class.

Honourable Mention has been made of MM. ALEXANDRE and Son, France, for two "*Harmoniums à Percussion*;" A. MÜLLER, France, for two portable Melodians; and J. DEUTSCHMANN, Austria, for a Seraphine.

In this class may also be placed a novel kind of musical instrument, called the *Harmonine*, exhibited by the inventor, M. DE VILLEROI. This little instrument is about eight inches in length, and its scale, commencing on the lowest C of the violin, comprises three octaves, including all the semitones. Considering the very small dimensions of the harmonine, its tone possesses a remarkable power, but at the same time is of an agreeable quality, somewhat resembling that of the oboe and flute. Its capabilities of imitating the distant sounds of an organ, and of producing every species of accentuation, also merit notice, as displaying considerable ingenuity on the part of the inventor.

*Instruments of Percussion.*

In this department, comprising Drums, Cymbals, &c., the Jury have noticed a variety of improvements of considerable importance, in the mechanism for tuning drums, for orchestras and military bands. For these improvements Prize Medals have been granted to Messrs. C. WARD (included in the award to him for a bassoon), United Kingdom; A. KNOCK, Zollverein. And Honourable Mention has been made of C. REXER, Zollverein; also of four very large and fine Gongs, exhibited by THE HONOURABLE EAST INDIA COMPANY.

*Automatic Instruments.*

In this class, comprising Mechanical Organs, &c., Mr. BRYCESON, of London, has exhibited a Barrel-Organ, for which the Jury have awarded a Prize Medal.

Other ingenious instruments of a similar description have been exhibited; and Honourable Mention has been made of Mr. C. DAWSON (for a barrel-organ, called an *Autophon*, the tunes of which are produced by means of perforated sheets of mill-board), Messrs. GRAY and DAVISON (for a barrel-organ), Messrs. WEHRLE and

STREUBERT, London (for a self-acting organ, manufactured by F. WEHRLE, Black Forest, Baden), United Kingdom.

*Miscellaneous Articles in connection with Musical Instruments.*

In this class are included tuning-forks, tuning-hammers, pitch-pipes, wire-strings, violin, viola, and violoncello bows, rosin for bows, musical diagrams for various purposes, miniature models, metronomes, specimens of

wood and felt for musical instruments, &c. The Jury have made Honourable Mention of Messrs. J. DODD (for violin, viola, and violoncello bows, and for covered strings for violins, violoncellos, and harps), E. DODD (for violin, violoncello, double-bass, and harp-strings), E. GREAVES (for a chromatic tuning-fork), United Kingdom; Messrs. SIMON and HENRY (for violin and violoncello bows), France; A. INDRI (for violin, violoncello, double-bass, harp, and guitar strings), Venice.

### REPORT ON HOROLOGICAL INSTRUMENTS.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

#### Jury.

E. B. DENISON, M.A., *Chairman and Reporter*, 42 Queen Anne Street. (Juror Class X.)  
 BARON ARMAND SEQUIER, *Deputy Chairman*. France. (Juror Class X.)  
 PROFESSOR DANIEL COLLADON. Switzerland. (Juror Class X.)  
 E. J. LAWRENCE, M.A., 44 Chancery Lane.

THE marine chronometer may be considered the most important of all machines for measuring time; and it is also the one in which an invariable rate of going is of the most consequence, inasmuch as longitude at sea is determined by means of chronometers, and they have frequently to go for a longer time without the means of being corrected by astronomical observations, than astronomical clocks, which are generally accompanied by fixed transit instruments.

It will probably appear strange that we have not awarded any Council Medal for chronometers, of which there are a considerable number in the Exhibition, especially in the English part, some of them by makers of the highest reputation. It is, however, this very circumstance which has rendered it impossible to make any such award; not only because we are directed by the Royal Commissioners to avoid the attempt to distinguish one article from others of the same kind, merely on account of superiority of execution, but because, among several of the best makers, there really is no one who could properly be so distinguished above all the rest.

The principles of the construction of chronometers have now been settled for some years without any material variation, except in one point, which will be mentioned presently, and there is hardly any visible difference between one good chronometer and another; it was hence obviously out of our power to make such actual trial of them as can only be conducted in an observatory, and must be continued for a considerable time in order to ascertain their relative merits.

We therefore came to the conclusion that the only satisfactory plan on which we can distinguish any among the large number of chronometers in the Exhibition (at least in the English part of it), is to adopt the results of the trials at the Royal Observatory, during the last few years, of chronometers by the same makers as have now sent any to the Exhibition. But it must be understood that the same reports of the Greenwich trials which justify us in awarding prizes to several chronometer-makers who are exhibitors, show that others who are not exhibitors would have been equally entitled to Medals if they had sent any chronometers here. The exhibitors who have been awarded Prize Medals from having obtained high places in the trials at the Royal Observatory in the last few years are—Messrs. DENT (No. 56, p. 413), C. FRODSHAM (No. 57, pp. 414, 415), PARKINSON and FRODSHAM (No. 55, p. 411), HUTTON (No. 7, p. 407), and ROSEBY (No. 12, p. 408); and we should have been glad to have the opportunity of similarly acknowledging the merits of Messrs. POOLE, E. J. MASSEY, and EIFFE, as the makers of chronometers, which, together with those of Loseby and Dent, have exclusively occupied the first three places in all the trials of the last four years.

Among the foreign chronometer-makers we have had the satisfaction of being able to award Prize Medals to three of the highest reputation in their respective countries, viz., M. VISSIERE, of Paris (No. 733, p. 1215), M. URBAN JÜRGENSEN, of Altona (No. 17, p. 1356), and M. LOUIS RICHARD, of Neuchâtel (CL. 1., Zollverein)

(No. 342, p. 1070); the last of whom has exhibited a chronometer in which the necessity for a fusee is superseded by a remontoire escapement of a more simple construction than usual, the impulse being given to the balance, not by any teeth of a scape-wheel, but by a small spring which is wound up sufficiently for the purpose by the scape-wheel every time it escapes.

The single point in which there is any material difference in the construction of the best chronometers, is the mode of effecting what is called the secondary or auxiliary compensation of the balance, or that which is required in addition to the ordinary compensation, to prevent the chronometer from gaining at mean temperatures if it is adjusted for two extreme ones, such as 20° and 100°, or losing at the extremes of heat and cold if the compensation is adjusted only for temperatures within moderate limits, as from 40° to 80°.

The earliest inventions for this purpose, as well as the discovery of the necessity for a secondary compensation, appear to have been made by Mr. Eiffe and Mr. Dent about the same time, and independently of each other; and their methods are still in use, and evidently very successful. But we agree with the opinion expressed by the Astronomer Royal in a report made by him to the Admiralty, that the most ingenious contrivance for this purpose, and probably the best adapted to the wants of chronometers—at least of those which are likely to be exposed to extreme temperatures—is Mr. LOSEBY'S (p. 408), in which small curved thermometer tubes are set upon the ends of the ordinary compensation bars, so that the mercury advances along the tubes towards the centre of the balance, and at an increasing rate the nearer it approaches the centre. The effect of this, as of most of the other contrivances for the same purpose, is evidently to diminish the moment of inertia of the balance still more than it is diminished by the beuding inwards of the ordinary compensation bars, on the ends of which the mercurial tubes are fixed.

The three makers who have been mentioned in addition to those who have received Medals not being exhibitors, we can give no account of their methods of compensation. Mr. DENT'S (p. 413) consists in placing the balance weights on small additional compensation bars set on the ends of the common ones, in such a position that the weights advance and recede in a radial direction more rapidly the nearer they are to the centre, for any given number of degrees of heat. There is also a chronometer exhibited by Messrs. BARRAUD and LUND (No. 34, p. 411), with a contrivance which is substantially the same in principle, and perhaps equally likely to answer, though not so simple in form; besides others which do not appear to us to require particular notice.

We desire to draw attention to a chronometer with a glass balance and balance-spring, exhibited by Mr. Dent, on account of the remarkable fact that such a spring only requires about one-tenth of the compensation of a steel spring, and one-twelfth of a gold one. We have been furnished with a copy of the Observatory report of the rate of a chronometer with this balance and spring,

and the small amount of compensating materials which it requires; and the variation of rate during the five months it was tried was very small. It is necessary to add, however, that Mr. Dent told us that some difficulties in making these glass springs have hitherto prevented their being generally used, even by himself; and we mention these facts in the hope that he and other persons may be thereby induced to exert their ingenuity in overcoming these difficulties, so as to bring into use a material for springs which requires so little compensation, and consequently no secondary compensation, and which is also free from liability to rust, a point of manifest importance in instruments to be used at sea.

#### *Astronomical Clocks.*

Among these clocks, which are also sometimes called *regulators*, there is little that requires special notice. There are several of the usual construction, with Graham's escapement and mercurial pendulum, by the eminent makers who have already been noticed, as well as by some others, both English and foreign. But astronomical clocks which will go accurately within two or three seconds a week may now be had of all good clock-makers; and it would be absurd to give a prize to any one for sending an instrument here, which a hundred other persons could have sent if they pleased; except in a few cases, such as that of chronometers above mentioned, where the exhibition of an article, not in itself distinguishable from others of the same kind, has enabled us to make a proper acknowledgment of the well-established reputation of the maker.\*

Besides these astronomical clocks of the usual construction, there are several with new escapements, chiefly on the remontoire principle, but none that appear to us likely to supersede the old dead escapement. We have nevertheless given Prize Medals to Mr. GOWLAND, of London (No. 27, p. 410), and M. GANNERY, of Paris (No. 516, p. 1203) for gravity escapements, which are substantially the same; the impulse being given in both of them, not by arms turning on pivots, but by small weights, which in M. Gannery's clock are hung by threads to the pallet arms, but in Mr. Gowland's are still more independent, being small inverted cups resting on the pallet arms, and alternately taken up by spikes projecting upwards from another pair of arms attached to the pendulum: on the other hand, in M. Gannery's escapement there is less tendency to *trip*; and it ought to be known to the inventors of remontoire escapements, that independently of the risk of actual tripping (or letting two or three teeth slip past at once), any tendency to drive the pallets too far, if the force of the clock happens to increase, is fatal to the accurate performance of such an escapement.

It should be added, that Mr. Gowland claims as an advantage of his escapement (and M. Gannery may do the same, and so may M. Wagner for one of his turret-clocks, which will be noticed afterwards) that the pendulum is independent of the friction of unlocking, because that is done by the little remontoire weight, which is stopped for a moment as it descends on to the pallet arm by reason of the inertia of the pallets and their arms. This was also the case in the late Captain Water's escapement, which is described in the Transactions of the Royal Society, but is too complicated for use. And indeed the contrivers of all such escapements should remember, that

\* It is a bare act of justice to the other exhibitors to mention, that in this desire to acknowledge the reputation of makers whose works have been tested by a much better criterion than we had the means of applying, we were nearly misled into giving a Medal to an exhibitor of astronomical clocks and watches, on the ground of his being really, as he very conspicuously designated himself, "Maker to the Royal Observatory." We fortunately ascertained from the best authority that the only ground on which this person so distinguished himself from all the other exhibitors was, his having once performed certain services for the Observatory establishment, by no means of a high order, and even those performed in such a way that they have been discontinued, and are particularly unlikely to be resumed.

no new escapement has any chance of coming into use unless it is as cheap and easy to make, as Graham's, and is really so independent of the force of the train that a common house-clock movement will do as well for it as a well-finished train with high-numbered pinions: an experiment which the makers of remontoire escapements seldom venture upon.

We have also given a Prize Medal to M. DUBOIS, of Locle (No. 9, p. 1266), the only Swiss maker who has exhibited a pendulum clock, for a regulator, with a grid-iron pendulum in which the compensation is adjustable, and an escapement, which is a sort of imitation of the chronometer escapement. A construction of much the same kind was suggested by Mr. Airy, in the Cambridge Philosophical Transactions, in the year 1837; and we do not mean, by giving this Medal, to express any opinion on the probability of such an escapement superseding the ordinary one.

Besides these escapements, which are all intended exclusively for astronomical clocks, there is one lately patented by Mr. C. MACDOWALL (No. 68, p. 417), which is intended as a substitute, not only for Graham's escapement, but for the common recoil escapement; and we are informed, as a proof of its cheapness, that a tender has been made to supply clocks to a public office, either with this escapement, or the usual recoil escapement, at the same price. Instead of a scape-wheel there is only a small disc, with a single ruby pin set in it, very near the arbor: the disc turns half round at every beat of the pendulum; and the pallets are both together on an arm, which may be the crutch of the pendulum, or may be in the pendulum-rod itself; and they are so formed, that the impulse is given chiefly by direct action across the line of centres, and not obliquely, as in all the anchor escapements, and therefore with less friction. It is also a dead escapement, and by the simple addition to it of two long teeth or arms for the locking part (on the principle of the duplex escapement in watches), the friction on the dead part of the pallets may be reduced almost to nothing, in clocks intended for very accurate performance. Mr. Macdowall is now making a clock with a remontoire escapement, on the same principle, which may evidently be as well applied to such an escapement as to impulse escapements. He has also successfully applied it to a lever-watch.

The greater velocity of the disc than of a scape-wheel renders another wheel in the train necessary; but as the clock, notwithstanding, goes with even a less maintaining force than usual, the friction of this extra wheel is evidently compensated by the diminished friction of the escapement, in consequence of the impulse being given directly instead of obliquely.

We are quite aware that an escapement, in general appearance similar to this, was made some years ago, both in England and France; and specimens of it were produced to us from each country. But in both those specimens there was a roller instead of the fixed pin in the disc; and, what is perhaps of more consequence, they both had a much larger angle of escape than Macdowall's clock, and consequently, required a larger vibration of the pendulum: and we are not surprised that escapements so made had never come into general use, which was admitted, with respect to the French one; or had been abandoned, as those who produced the English one assured us that it had been long ago. Mr. Macdowall's escapement avoids the *shake* and the uncertainty of a roller, and does not require a larger arc of vibration than a common clock; and, on the whole, we think that it combines, in a high degree, the several qualities which we are directed to regard in our distribution of prizes, viz., simplicity, cheapness, durability, and at least probable accuracy of performance, and therefore we have given Mr. MACDOWALL (No. 68, p. 417), a Prize Medal for what he calls his "single-pin escapement."

#### *Turret-Clocks.*

After astronomical clocks, those which are intended for public buildings are of the greatest importance. Indeed, in some public clocks a degree of accuracy may now be properly required, as it can be obtained, exceed-

ing that of most astronomical clocks. Considering the number of persons who make turret-clocks in this country, the smallness of the number of them in the Exhibition is rather surprising; and those which deserve any favourable notice are still fewer. It is remarkable, too, that the only ones in the English Department which appeared to us to deserve such notice, are two clocks with cast-iron wheels; and they are both of them such as ought to convince anybody, that the prejudice against cast-iron clock-wheels is altogether unfounded, now that they can be made so well that the teeth do not even require touching with a file after they come out of the mould. Both of these clocks also have a remontoire apparatus in the going train, the effect of which is, that the escapement is driven, not by the great clock weight, but by a small weight, or a spring, wound up at intervals by the train, which is discharged like a striking part, or in some other way, at every minute or half minute, by the revolution of the scape-wheel. Most of the turret-clocks in M. WAGNER'S collection (No. 736, p. 1215), which will be noticed presently, are also on the remontoire principle. And there can be no doubt that, since it can be applied at a moderate expense, all turret-clocks of high character, at least if they have large external dials, ought to be so made, because it renders the escapement independent of all variations in the force of the train, which are sometimes very considerable, and also allows a sufficient weight to be applied to the clock to drive the hands in all weathers, without making the pendulum swing too far; and moreover, as the hands of a clock of this kind do not move an almost invisible quantity at every beat of the pendulum, but by a very sensible jump at every letting off of the remontoire, the time can be taken from the minute-hand, at a considerable distance, as accurately as from the seconds-hand of a regulator; and for the same reason the striking part is also discharged more exactly at the right time.

As regards the going part, the principal advantage of cast-iron wheels over brass or gun-metal is their much greater cheapness. But in the striking part they have the further advantage of greater strength, which, in large clocks, is the chief thing to be attended to, and the thing in which they are most frequently deficient. In Mr. ROBERTS'S clock the striking is done on a new plan, with a very light hammer; but the clock has only a small hemispherical bell attached to it, and we have no proof that this very ingenious contrivance, in which neither fly nor hammer-spring is required, would answer for a large bell, such as that on which Mr. DENT'S clock strikes, or even a much smaller bell of the usual form. In the latter clock the hammer is raised by broad cams cast on the great wheel of the striking part, and of such a shape, and with the lever so arranged, that there is the smallest possible waste of power: in fact, very little more than one-fourth of the force of the great striking weight is lost in friction, the resistance of the air to the fly, and in the necessary interval between the fall of the hammer and the beginning of its next rise,—a proportion which is much less than usual.

Both Mr. ROBERTS'S (No. 130, p. 422) and Mr. DENT'S (No. 55, pp. 413, 414) clocks have compensated pendulums. The former has a steel and brass compensation, which, Mr. Roberts says, is made in accordance with his own experiments on the relative expansion of the two metals; though it differs from the result of all the ordinary tables of expansion, the length of the brass compensation-tubes being much less than usual. Mr. DENT'S pendulum has an iron and zinc tube compensation, made according to the usual tables, and agreeing with his experience of the Royal Exchange clock pendulum, which has a similar one, and has now been sufficiently tested for several years.

Mr. Roberts's escapement is a new one of his own contrivance: the pendulum only receives its impulse on a roller at every alternate beat. The remontoire is on the endless chain plan, which is described in Reid's book on clock-making, except that the mode of letting off is different. The form of the clock-frame is pyramidal, with the pendulum hung from the top; and it is consequently very steady, provided the floor it stands on be

so; though the plan of fixing turret-clocks on beams let into the wall for the purpose, is, in most instances, steadier than any fixing to a floor can be. All the wheels are made to take out separately, as they should always be, and the Jury were particularly struck with the goodness of the casting and the form of the wheels. Mr. Roberts is well known as an eminent engine-maker at Manchester, and by the application of his machinery to the manufacturing of these clocks he is able to sell them at a much lower price than usual. On the whole, without expressing any opinion on the supposed advantages of the escapement, or the mode of striking, or some other peculiarities of this clock, we consider it well deserving of a Prize Medal.

The escapement in Mr. Dent's clock is the ordinary pin-wheel dead escapement, but the wheel is smaller than usual, being only four inches in diameter, and it contains forty pins. It is driven by a spiral spring, which is merely part of a large watch-spring, and is wound up a quarter of a turn after every quarter of a turn of the scape-wheel. The pinion, or small-wheel to which one end of the spring is fixed, does not ride on the arbor of the scape-wheel, in which case there would be considerable friction between them, but on a stud fixed into the clock-frame; so that the scape-wheel is driven by the spring without any friction whatever, except that of its own pivots, and the very small friction which is due to the upward pressure of the ends of the remontoire fly on the arbor of the scape-wheel. The consequence is, that there cannot possibly be any variation in the force on the pendulum, except that which may arise in the escapement itself, if the pallets are not properly oiled,—as in all other anchor or pin-wheel escapements. It may be worth while to state that the variation of force in the spring due to changes of temperature, if it were ten times as great as it is, would produce no sensible effect upon the pendulum. And as this pendulum is eight feet long, and weighs above two cwt., such a clock may be reasonably expected to go as well as any astronomical clock; and, in fact, it has gone since the opening of the Exhibition, at least as well as a highly-finished astronomical clock, which was placed by the side of it, and every week compared with the time brought from Greenwich.

The maintaining power for keeping it going while winding is of a new construction; as the common spring-going barrel is difficult to construct with both sufficient play and sufficient power for large clocks of this kind, which take several minutes to wind up. This maintaining power is of the "bolt-and-shutter" kind, but not requiring any click, and so made that it is impossible to begin winding without raising the maintaining weight high enough to keep in action for seven or eight minutes, and yet it can be thrown out of gear as soon as the winding is done. There is another point in which the arrangement is different from usual: the great wheel and barrel of the going part, and of both the striking parts, are set in the great frame, and the smaller frame, which carries all the other wheels of the going part, can be taken off entire, without disturbing either the great wheel or the pendulum. Mr. Dent uses wire ropes, because by that means he obtains the advantage of many turns of the barrels in the eight days, without the inconvenience of long barrels, or the bad practice of letting the rope go twice over them.

A Council Medal has been awarded to Mr. DENT (p. 413) for this clock, on the recommendation of all the members of this Jury, except the Chairman, who declined to express an opinion upon it, on account of having himself furnished the design. But as it contains hardly anything which had not been either previously used by Mr. Dent, or suggested in print, and therefore equally open to the adoption of any other maker, he is entitled to full credit for it, as well as for his enterprise in attempting to

Since the close of the Exhibition, we have been informed that the accumulated error of the large clock, from the 8th August to the 15th October, was — 2.8 seconds; or, in other words, the pendulum lost not quite two beats in the four millions of vibrations it performed during that period.

introduce a new description of clock, possessing both greater accuracy and greater strength than usual, and one which can be made for less money than equally large turret-clocks, of the common construction and of good quality.

We have already referred to M. WAGNER's (of Paris) (p. 1215), collection of turret-clocks which displays great fertility of invention; and we have awarded him a Council Medal for the collection, but especially for his clock with a continuous motion, intended for the purpose of driving equatorial telescopes, so as to keep them pointed at any given star, and for all other purposes for which a continuous, instead of an intermittent motion is required. The mode by which this is effected is particularly ingenious as well as simple. In this, as in several others of M. Wagner's clocks, there is a gravity remontoire apparatus, on the bevelled-wheel principle, on the arbor of the wheel below the scape-wheel. For the construction of these remontoires we must refer to books, as it would be difficult to give an intelligible description of them without drawings; but assuming that to be understood, the arm which carries the remontoire weight is in this clock prolonged to a convenient distance, so as to carry a kind of bell hung to it by a couple of wires, and within the bell a fly is driven by a train of wheels connected with the great wheel of the clock. This fly is so adjusted, that the velocity with which it allows the train to move is equal to the average velocity which it would have if connected with the pendulum, or to the velocity of a train with a revolving instead of a vibrating pendulum, of the same period. If the force on the clock be too great, the remontoire arm becomes raised above its average height, and the bell rising with it lets in more of the external air upon the fly, which reduces its velocity, and *vice versa*. In this way, the hand, or telescope, attached to that part of the train which has the continuous motion, is always made to keep pace with the average velocity of the scape-wheel with its vibrating pendulum.

M. Wagner has exhibited a movement of this kind applied to a long vertical barrel for measuring the force of gravity, as in Attwood's machine. The barrel revolves in a second, and by the side of it a weight descends freely in a groove, with an inked brush attached to it; and as the barrel revolves, the falling brush traces a curve on the surface, which exactly indicates the space descended in any given portion of the time which the barrel takes to revolve.

Two of M. Wagner's turret-clocks have this same bevelled-wheel remontoire in the train, only with a provision for letting it off at every half-minute, instead of a continuous motion; and one of them has a remontoire escapement also, but by no means incapable of tripping, if the force is increased.

There is another clock in the same collection which deserves particular notice on account of there being a remontoire in it, without any additional wheel in the train. This is managed by setting the second wheel in a swinging frame, having its axis in a line with the arbor of the scape-wheel, and so allowing a little play sideways to the arbor of the second wheel. In this clock, also, the pallets are set in the pendulum without any crutch, the scape-wheel being put outside the frame.

Another of M. Wagner's clocks has an escapement with a direct recoil, as in Harrison's once famous but long ago abandoned escapement; and in this clock, also, the pallets are set on the pendulum without a crutch. It is certainly a superior contrivance to Harrison's; although, as in his, the recoil is necessarily very great and sudden.

All the smaller clocks in this collection have cast-iron striking parts, though the two large ones are of brass, probably for the sake of appearance; and they all strike from the great wheel, like Mr. Dent's clock; but most of them have two hour-hammers, striking alternately, and none of them appear to have barrels of sufficient length, in proportion to the number of striking pins, to go a week without the rope going twice over the barrel. They have also compensated pendulums, all on the lever principle; in some cases applied to the pendulum rods, and in others fixed to the bar at the top of the clock-frame, so as to draw up the pendulum spring through a slit in the clock.

The lever compensation seems to be the only one used in France, except occasionally the gridiron pendulum, with nine bars of brass and steel. In English clocks, hardly any compensation is now used, except the mercurial cylinder in the best astronomical clocks, and the zinc tube compensation in clocks where the mercurial pendulum would be too expensive.

We have given a Prize Medal to M. GOURDIN (p. 1204), a maker of some celebrity in France, for a small well-executed turret-clock, with a train remontoire of a different construction from any of M. Wagner's, the remontoire wheels being employed in changing velocity, or as part of the clock train, and not merely in changing direction, which is the case in the bevelled-wheel remontoire.

There are also some small turret-clocks, both by M. CHAVIN (p. 1200) and by M. BAILLY COMTE (p. 1197), which we mention on account of their extraordinary cheapness.

Electrical clocks may be considered as connected with turret-clocks, especially in this Exhibition, in which the experiment has been made of working three large dials by electricity, not merely as a means of connection with one large clock driven by a weight in the usual way, but using electricity as the motive power. It is needless to inform any one who has frequented the Exhibition, how far that experiment has been successful; but whenever the practical difficulty is overcome, of obtaining unfavourable electrical action, *i. e.*, of securing perfect contact of the wires at every proper epoch, there is no doubt that some kind of remontoire action will be the proper way of maintaining the motion of the pendulum, as has been attempted by Mr. SHEPHERD (pp. 419, 422) in these clocks, and by several other exhibitors. The other plan, of making the pendulum drive the train, cannot possibly avoid such variations of force as will be fatal to the isochronism of any clock pendulum.

There is no instance in the Exhibition of a large weight-clock driving dials at a distance by electrical connection, either galvanic or magnetic; although there is not found to be any difficulty in doing it by the latter method, by a strong permanent magnet, such as in Henley's magnetic telegraph, set on an axis, so that it can be twisted out of contact with the armature by the force of the great clock, whenever the remontoire is let off. The wires are coiled round the armature, in the well-known manner which is employed in telegraphs of this kind; and they make and unmake the temporary magnets placed behind every dial, of which the hands are to be kept in motion with those of the great clock by means of ratchet-work, or pallets, worked by the alternations of the temporary magnets, just as in the two electrical dials in front of the South and West Galleries.

#### House Clocks.

In what are called by the French civil clocks, or clocks for domestic use, there is not much room for difference, except in the merely ornamental parts, which we have nothing to do with. There are many such clocks, of various shapes, in the English part of the Exhibition, as well as the foreign, and most of them sufficiently good for their purpose. But it is impossible to distinguish any of the English ones as manifesting such superiority over the rest as would justify us in giving Medals for them, because such Medals could only mislead the public into the belief that there are not many other makers from whom equally good house clocks may be obtained: indeed, some of the best makers have not thought it worth while to exhibit any.

Among the French exhibitors, however, we have given a Prize Medal to Messrs. DETOUCHE and HOUVIN (p. 1253), who exhibit a very handsome collection of well-made clocks, of various sizes, some with compensated pendulums and uncommon escapements, and with what is called *equation work*, or a hand to show solar as well as mean time. They also exhibit some of their pinions separately, which are very well made. Altogether, their collection is well worthy of notice.

We have also given a Prize Medal for small clocks to M. BROUOT (p. 1199), the originator of an elegant and popular form of a nearly dead escapement in ornamental

clocks, in which the pallets consist of semi-cylinders of jewels, at right angles to the plane of the scape-wheel. These clocks are generally made with the escapement in front of the dial, so as to be visible, and also to allow the scape-wheel to be taken out without disturbing the rest of the clock.

In addition to these Medals, which we have awarded chiefly on account of the good execution or arrangement of the movements, we have given one to Messrs. KEYNER and COLIN (No. 984, p. 1226), who exhibit a number of house clocks of various kinds, all remarkable for the lowness of their price, and sufficiently well executed for the ordinary uses of such clocks. And in speaking of cheap house clocks, of course the American clocks ought not to be unnoticed, though we have thought it unnecessary to attempt to distinguish any of them by a Prize Medal, as they are all substantially alike; and they are now so universally known for their cheapness—a quality which generally receives its own reward—that the additional distinction of a Medal on that account would be more than usually superfluous. There is, however, one quality for which they are entitled to greater credit than is generally known, and that is the small weights or moving force which they require, showing that there is much less power wasted by friction and the inertia of the train than in most other clocks. The small amount of inertia is caused by the lightness of the wheels; and the small friction (which certainly cannot be attributed either to the high finish or high numbers of the pinions) is accounted for by the use of lantern pinions, which (when driven by the wheels) have much less friction than leaved pinions of such low numbers, and are also less liable to be clogged with dirt, and are less affected by the wheel-teeth being inaccurately cut, as they generally are in clocks of much greater pretension than these.

To this class of domestic clocks belong the various forms of striking and chiming clocks, and alarms, and also tell-tale or watchmen's clocks, and clocks going a long time without winding, and perpetual almanac clocks, whatever be the number of phenomena which they profess to show. There is now so little difficulty in making these things, and so little use in most of them when made, that we do not think it necessary to distinguish any of them by a Medal, although in some instances they display ingenious contrivances for effecting their different objects. The Jury, however, agreed to mention some small alarm clocks by M. PIERRETT, of Paris, (No. 958, p. 1225), on account of their cheapness, and because alarms really are, for certain purposes, useful articles of household furniture.

#### Watches.

The only horological instruments which remain to be noticed are watches, in which term are included carriage clocks, since these are, in fact, only large watches, set in cases like those of small clocks, and with the balance placed at right angles to the rest of the wheels, so that its axis may stand vertically, because it vibrates with less friction in that position—a fact of which some of the exhibitors do not seem to be aware.

Watches, like house clocks, are so much an article of general manufacture, and there is so little difference in the quality of those of several of the best makers, that it is difficult to establish any principle on which prizes can be given for them, except with reference to the general reputation of the exhibitors of articles which appear in themselves to be good.

The three principal places in England where watches are made, are London, Liverpool, and Coventry. Among the London makers, several who have received Medals for chronometers or other articles, would have been entitled to receive them for their exhibition watches alone. There is a very beautiful collection of carriage clocks and watches, of various kinds, by Mr. DENT; some of them exhibiting, besides the compensated balance, which all first-rate watches now possess, a contrivance (different from most others for the same purpose) for winding up and setting the hands without a key, by turning the knob in the handle of *pendant*; and others having what is called a split seconds-hand, that is to say, two seconds-

hands, which travel together and appear as one, till you move a pin in the case, whereupon one of the hands separates from the other, and stops until you move the pin again, when the hand starts forward and rejoins the proper seconds-hand, after any length of stoppage; and this is done without the use of an independent train to drive the extra seconds-hand. There are various contrivances, of different kinds, for the same purpose, among the other watches in the Exhibition. Mr. Dent also exhibits a night-watch, or a watch for blind persons, technically called a *tac*-watch, with an external hand, which moves round with the hour-hand, and the position of which can be felt with tolerable accuracy, with reference to twelve studs set round the rim of the case, for the twelve hours, reckoning of course from the handle. There is also a watch similar to this among the Swiss ones; but Mr. Dent's has a special provision to prevent the position of the hand from being altered by the act of feeling it. He is to be considered as entitled to a Prize Medal for his collection of watches, independently of the Council Medal awarded to him for the large clock.

In like manner the Prize Medals awarded to Mr. C. FRODSHAM (No. 51, pp. 414, 415), and Messrs. PAR-KINSON and H. FRODSHAM (No. 35, p. 411), for chronometers, are to be understood as awarded also in respect of their exhibition of watches.

The former of these exhibitors states that his watches are made on a certain *caliper* (as the watchmakers call the working plan of a watch), in which the sizes of the wheels are determined according to a set of rules, partly arbitrary and partly founded on experience, according to the size of the barrel, or, in other words, according to the power of the mainspring. All makers of watches on a large scale must have some such system of their own; but Mr. Frodsham proposes that a general system shall be adopted, in which the sizes of the various pieces of a watch shall not be expressed by the usual conventional numbers, known only to those who have to use them, but in decimals of an inch, and according to certain tables of proportion with reference to the size of the barrel, as above mentioned. It would probably be convenient if some such system were adopted, either according to Mr. Frodsham's rules (so far as they are arbitrary), or any others which might be generally agreed on.

Such a system as this is still more completely carried out by Mr. ROBERTS's watch-plate drilling machine (No. 130, p. 422), a most ingenious and apparently successful invention, by which any given caliper or proportion of the parts of a watch of any size can be at once transferred, by a mere mechanical process, to any other watches of any other sizes; piercing all the holes required for the pivots of the wheels, and other purposes, with unflinching accuracy. And in connection with this machine there is a *sector* for proportioning the sizes of wheels for any required number of teeth, also by a mechanical operation without the necessity of calculation. The Prize Medal before mentioned as given to Mr. ROBERTS (p. 422) for his cast-iron clock is therefore to be considered as awarded equally in respect of his watch-plate drilling machine.

It should be mentioned also that he exhibits some watches with a remontoire escapement, and one, which he calls a *recorder* watch, with two seconds-hands, of which one can be stopped to denote the exact time of any observation, as is done in various other watches in the Exhibition. Indeed, the number of them is so great that we have not been able to give a Prize Medal to any maker solely on account of such a contrivance, except to M. RIEUSSEC (No. 1685, p. 1257), a well-known watchmaker of Paris, for his watches with a seconds-hand, which, on touching a pin at the time of observation, makes a black spot on the dial; and this can be repeated at very close intervals, so as to record the exact epochs of a number of observed phenomena succeeding each other very closely, without the necessity of taking the eye off the object to be watched for in order to look at the dial.

What are called the *movements* of watches and small clocks are made by machinery, on a very large scale, by MM. JAFFE BROTHERS, of Paris (No. 275), to whom we

have awarded a Council Medal; although the objects themselves, as they appear in the Exhibition, are by no means striking, inasmuch as these watch movements are in fact only the two plates and some of the larger wheels of the train, and the clock movements are the internal parts of the clock without the escapement. The most, indeed the only, remarkable quality in these movements, is their extraordinary cheapness. They are, however, at least as good as any others of the same kind made in the usual way by hand; and Messrs. JAPY, we are told, sell no less than half a million of them to watch and clock-makers in the course of a year. The great cheapness of these articles being obtained by means of a peculiar process of manufacture, it was considered that Messrs. Japy might properly receive a Council Medal for their watch movements, as a specimen of the produce of such improved mode of manufacturing.

Messrs. ROTHERHAM, of Coventry (No. 124, p. 419), exhibit a large collection of watches in all stages of manufacture, for which we have awarded a Prize Medal. We have also given one to Mr. ROSKELL, of Liverpool (No. 123, p. 419), an eminent maker, who exhibits a handsome collection of watches and small clocks, some of which are so constructed as to show the action of the various forms of watch escapements in general use; and to M. BÉDIER, of Paris (No. 1425, p. 1244), for a cheap kind of watch alarm, of which a great number are sold both in France and in this country.

It may be mentioned here that M. KORALIK, of Pesth (No. 169, p. 1016), exhibits a set of models, in which thirteen different escapements can be fitted to one clock movement, by merely unscrewing the part containing the escapement. This is apparently intended for illustrating lectures on watchmaking, or for experiments on the effects of different escapements.

Mr. JACKSON exhibits what he calls (with some disregard of etymology) a *solid* watch (No. 32, p. 411), whereby he means a watch with a solid key. However, his invention of the thing fortunately deserves more credit than his name for it. Most people are aware that the pipes of watch-keys wear out; and, in so doing, they wear off the corners of the winding square on which they act. The shorter this winding square is, the sooner of course this will happen; and in thin watches of the common construction the winding square cannot but be short. With the view of avoiding this, Messrs. AUDERT and KLAFENBERGER's watches (No. 52A, p. 412), and several foreign ones in the Exhibition, which have no fusee, have the arbor of the barrel hollow and squared for a solid key to fit into it the whole depth of the barrel. But this will not do for watches with a fusee, because the fusee arbor has to turn while the watch is going, though the barrel-arbor of a watch without a fusee only turns while it is being wound up; and a hollow fusee arbor would be much too thick. Mr. Jackson, therefore, winds up his fusee by a small auxiliary wheel, analogous to what is called a jack-wheel in turret-clocks; and the arbor of this small wheel is made hollow and squared to receive the solid key. As the little wheel has nothing to do, and no pressure on it when the watch is going, the friction of its thick arbor is inconsiderable, even supposing it not to be thrown out of gear, as it might be. This also allows the fusee arbor to be smaller, and therefore to turn with less friction than usual. We have consequently given Mr. Jackson (p. 411) a Prize Medal for this invention.

We have also given a Prize Medal to M. MONTANTON, of Paris (No. 601, p. 1207), for his mainsprings, of which he is a maker of high reputation; and it is unnecessary to say that the goodness of the mainspring is of great importance to the accurate performance of watches, especially of foreign ones, in which there is generally no fusee, and so the spring must be capable of acting with nearly uniform force for four or five turns of the barrel.

We agreed to mention the names of two other French watchmakers: M. LE ROY (No. 1186, p. 1234), for a collection of well-finished clocks and watches; and M. LAUMAIN (No. 292, p. 1190) who exhibits some well-made pocket chronometers, with the escapement part made to take off separately: as well as the name of Mr. BOLTON

(No. 94, p. 418), an English exhibitor of some very cheap watches in German silver cases.

The Swiss exhibition of horology consists entirely (with the single exception of a clock before mentioned) of watches and watch-work; and, as is well known, a large proportion of the watches of the world, especially the small and cheaper ones, are made in Switzerland. But in this instance, as in some others, it is not to be inferred that we intend the superiority of the works of one nation over another, in any particular department, to be measured by the number of medals which have been awarded to each, as they were given on no such consideration.

We have given Prize Medals for watches to the following Swiss exhibitors:—Messrs. AUDEMARS (Switzerland, No. 22, p. 1267), GRANDJEAN (No. 8, p. 1266), GROSCLAUDE (No. 24, p. 1268), LECOULTRE (No. 262, p. 1243), MERCIER (No. 175, p. 1277), PATEK and PHILIPPE (No. 99, p. 1273), and RETOR (No. 101, p. 1273), except that for the last a grant of money has been substituted.

M. AUDEMARS (No. 22, p. 1267) exhibits a watch with a contrivance for winding up the train which is required for driving what is called an "independent seconds-hand," as well as the ordinary train, by the handle or pendant, so that when either train is fully wound up, the winder acts on it no longer, but proceeds with the other train alone. He has likewise a watch with several dials, one of them indicating one-fifth of a second, and with provisions for stopping the different hands independently. It may be mentioned here that Messrs. COUSINS and WHITESIDE, of London (No. 86, p. 417), also exhibit a large watch with a stop seconds-hand, indicating one-sixth of a second. M. Audemars' collection contains various other watches, with different kinds of escapements and other peculiarities, which cannot be particularly described here.

M. GRANDJEAN (p. 1266) exhibits some pocket chronometers, i. e., watches with the chronometer escapement; and one of them has a balance-spring of a spherical form instead of a flat or a cylindrical one.

M. GROSCLAUDE (p. 1268) has sent some watches with "independent seconds-hand," and only a single mainspring.

M. LECOULTRE's (p. 1283) watches are remarkable for the good execution of the wheels and pinions. He is stated to make all his watches with the corresponding wheels of the same size, so that when any wheel is damaged, it can at once be replaced by a new one without any other trouble than that of putting it in. And he, like some other makers, has a method of winding up and setting the hands without a key, and with a provision to avoid the risk of a slight derangement of the hands in the act of putting their adjusting work in gear, to which some other methods are said to be liable.

M. MERCIER (p. 1277) exhibits among other well-made articles, a watch with a new recoiling escapement with a double scape-wheel, which is ingenious and simple; but we do not profess to give any opinion on the probability of its success.

MM. PATEK and PHILIPPE (p. 1273) exhibit a large and valuable collection of watches and pocket chronometers. Their articles are generally of moderate price, besides being well made, and some of them are highly finished. They have a repeater with two barrels, both winding in the handle, and a watch for the blind. They are the makers of the very small watch only 35 of an inch in diameter, which attracted much notice as the smallest in the Exhibition.

We have recommended M. RETOR (p. 1273) for a reward in money instead of a Prize Medal, as we understand that he is a person of very small means, who has had some difficulty in getting up the articles which he has sent to the Exhibition, and that he is also engaged in making experiments in watchmaking, which are of course at present unremunerative. He has exhibited a pocket chronometer with an ingenious escapement.

We conclude the notice of the Medals to the Swiss exhibitors of watches with the award of a Council Medal to M. LUTZ, of Geneva (No. 94, p. 1272), for his watch

balance-springs. \* On the balance-spring, more than any other single piece of a watch, its isochronism depends; and these springs present a marked difference in some of their qualities from those of any other exhibitor (even of some who specially directed our attention to the alleged superiority of their springs), inasmuch as they bore the tests both of heating and stretching out nearly straight without at all altering their permanent form, which was not the case with any other springs which we tried.

Besides these, we agreed to make Honourable Mention in our Report of the following Swiss exhibitors of watches:—ELFROTH (No. 78, pp. 1271, 1272), the maker of the small watch in the end of a pencil-case; Bock

(No. 31, p. 1268), COURVOISIER (No. 34, p. 1268), MERMooz (No. 15, p. 1266), and MESSRS. BARON and UHLMANN (No. 74, p. 1271); also of M. FAVRE BRANDT (No. 23, p. 1267), on account of his ingenious instrument for tracing out (not cutting) the teeth of watch-wheels in the epicycloidal form.

And lastly, we have awarded a Prize Medal to M. BENOIT, of Sardinia (No. 33, p. 1303), for his watches and watch movements, and for a machine for rapidly polishing the teeth of the scape-wheel of a horizontal or cylinder escapement.

The following is a summary of the awards in this Class:—

## COUNCIL MEDALS.

| NATION.        | Number in Catalogue. | NAME OF EXHIBITOR.  | OBJECTS REWARDED.  |
|----------------|----------------------|---------------------|--|
| United Kingdom | 55                   | Dent, E. J.         | Great clock and collection of other articles.                  |
| France         | 275                  | Japy Brothers       | Cheap clock and watch movements, made by machinery.            |
| Switzerland    | 94                   | Lutz, C.            | Hair springs.  |
| France         | 736                  | Wagner, J. (Nephew) | Continuous motion remontoire, and collection of turret-clocks. |

## PRIZE MEDALS.

|                    |      |                               |   |
|--------------------|------|-------------------------------|---|
| Switzerland        | 22   | Audemars, L.                  | Watches and watch movements.                        |
| Sardinia           | 33   | Benoit, A.                    | Watches and tooth-polishing machine.                |
| France             | 441  | Brocot, A.                    | Half-dead jewelled escapement.                      |
|                    | 1589 | D. touche and Houdin          | Collection of clocks.                               |
| Switzerland        | 9    | Dubois F. William             | Astronomical clock.                                 |
| United Kingdom     | 57   | Frodsham, C.                  | Chronometers and watches.                           |
| France             | 516  | Ganucy, V.                    | Astronomical clock.                                 |
|                    | 525  | Gourdin, J.                   | Small turret-clock.                                 |
| United Kingdom     | 27   | Gowland, J.                   | Astronomical clock.                                 |
| Switzerland        | 8    | Grandjean, H.                 | Pocket chronometers.                                |
|                    | 24   | Grosclaude, C. H.             | Pocket chronometers.                                |
| United Kingdom     | 7    | Hutton, J.                    | Chronometers.                                       |
|                    | 32   | Jackson, W. M. and S.         | Watches, solid key.                                 |
| Denmark            | 17   | Jürgensen and Sons            | Chronometer.  |
| Switzerland        | 25   | Lecoultré, A.                 | Watches, movements, and pinions.                    |
| United Kingdom     | 12   | Loebby, E. T.                 | Chronometer compensation balance.                   |
|                    | 68   | MacDowall, Charles            | Clock escapement.                                   |
| Switzerland        | 96   | Mercier, S.                   | Watches.  |
| France             | 601  | Montandon Brothers            | Watch mainsprings.                                  |
| United Kingdom     | 35   | Parkinson and Frodsham        | Chronometers and watches.                           |
| Switzerland        | 99   | Patek, Philippe, and Co.      | Chronometers, watches, &c.                          |
| France             | 1425 | Redier, A.                    | Cheap watch alarms.                                 |
| Switzerland        | 101  | Retor, F. (money prize, 50/.) | Pocket chronometer with new escapement.             |
| France             | 984  | Reydlor Brothers, and Colin   | Cheap house clocks.                                 |
| Prussia (1 Zollr.) | 342  | Richard, Louis                | Chronometer.  |
| France             | 1685 | Rieussec, N.                  | Watch with hand printing seconds.                   |
| United Kingdom     | 130  | Roberts, R.                   | Turret-clock, and watch-plate drilling machine.     |
|                    | 123  | Roskell, J.                   | Collection of models and watches, and small clocks. |
|                    | 124  | Rotherham and Sons            | Collection of watches.                              |
| France             | 733  | Vissiere                      | Chronometers.                                       |

## HONOURABLE MENTION.

|                |      |                          |  |
|----------------|------|--------------------------|--|
| United Kingdom | 52A  | Aubert and Klaffenberger | Watches.   |
| France         | 407  | Bailly-Comte and Son     | Cheap turret-clocks.   |
| Switzerland    | 74   | Baron and Uhlmann        | Chronometers and watches.  |
| United Kingdom | 31   | Barrard and Lund         | Compensation balance, and watches.   |
| Switzerland    | 31   | Bock, H.                 | Watches.   |
| United Kingdom | 94   | Bolton, T.               | Cheap watches.   |
| France         | 450  | Cham (Elder Brother)     | Cheap turret-clocks.   |
| Switzerland    | 34   | Courvoisier, F.          | Chronometers and watches.  |
| United Kingdom | 86   | Cousens and Whiteside    | Stop-watch.  |
| Switzerland    | 78   | Elfroth, D. H.           | Watch in pencil-case.  |
|                | 23   | Favre Brandt             | Watches and tooth-tracing machine.   |
|                | 23   | Favre, H. A.             | Chronometer, with pointing seconds-hand for marking minute portions of time. |
| France         | 292  | Laumain, C.              | Pocket chronometers.   |
|                | 1186 | Leroy and Son            | Carriage clocks and watches.   |
| Switzerland    | 15   | Mermooz, Brothers        | Chronometers and watches.  |
| France         | 350  | Pierret                  | Cheap clock alarms.  |
| United Kingdom | 128  | Shepherd, C.             | Electric clock escapement.   |

## CLASS Xc.

### REPORT ON SURGICAL INSTRUMENTS.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the  
OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

#### Jury.

J. H. GREEN, F.R.S., *Chairman and Reporter*, Hadley, Middlesex.  
Dr. THOMAS CHADBOURNE, United States.  
JAMES PHILIP, 67 St. James's Street; *Surgical Instrument Maker*.  
Dr. ROLX, France?  
Dr. LALLEMAND, France.  
W. LAWRENCE, F.R.S., Whitehall Place; *Surgeon to Bartholomew's Hospital*.

THE Jury have the honour of submitting to Her Majesty's Commissioners the following Report, under the impression that the task has been confided to them of furnishing an intelligible account, as far as may be derived from an inspection of the contributions to the Great Exhibition, of the present state and condition of the art of manufacturing surgical instruments.

The relation between the instrument employed and the scientific objects of the surgeon, is, however, so intimate and essential, that in order to arrive at a just conception of the scope of the instrument-maker's business and art, it will be necessary to make some brief observations on the purposes of surgical instruments, and on the conditions of what may be properly called improvement in connection with the art and science of surgery.

The instruments of the surgeon may be regarded as aids to those organs by which, on the one hand, man receives the notices of outward objects, and on the other, to those by which he reacts upon the external world—namely, his senses, and as the representative and vice-gérant of the motive powers, his hands. By this armature, then, of the senses and hands, and in proportion as it is efficient, is he endowed with the means of assisting and relieving those who require his services. There is, however, this peculiarity in the surgeon's instruments, that they are scarcely otherwise employed than in operations on living and sensible parts. To supply such aids as the surgeon requires is the business of the instrument-maker; often only as the mechanical artificer, but not unfrequently contributing, by his inventive ingenuity, to carry out more completely the surgeon's designs. The art of the instrument-maker has, indeed, a twofold character. He has, in the first place, to arm the operator for the various exigencies which his office implies—for example, with knives, saws, and the like, for removing parts which have been spoiled by violence or disease; with tourniquets, and other means, for arresting bleeding; with needles, for closing wounds; and with the various means for ascertaining the presence and for the extraction of foreign bodies; and, in the second place, he has to supply the needs of the mutilated sufferer, and to furnish compensation for defects, as far as such can be mechanically provided, in the shape of crutches, supports, and bandages, and of artificial eyes, palates, and even limbs. He must be then an able mechanist, and such, be it said to the credit of instrument-makers, he will generally be found. But with, and almost in proportion to, his mechanical ingenuity arises the danger that it will induce him to adopt in his works unnecessary mechanical refinement and pernicious complexity; for, if the principle above enunciated be correct, it may be admitted that the nearer any instrument, consistently with its use, approaches to the organic simplicity of the hand and fingers, unembarrassed by mechanical details and complex adaptations, the nearer will be its approach to perfection.

If we now turn to the progress of improvement in the construction of surgical instruments, it will be found

that, as it necessarily stands in intimate relation to the advance of surgical science, it cannot but exhibit a tendency to the same simplicity that characterises improved operative surgery—perhaps by discarding as useless a whole group of instruments, always by the gradual introduction of methods which require fewer and less complex instruments; or if the aid of new instruments be required, it can scarcely happen but that those answer their purpose best which are in accordance with the principles already laid down.

Let the surgical student look into any old book of surgery, with its quaint cuts and illustrations, such a work as Heister's, for instance, which is intended especially to afford information on the apparatus and instruments of this science,—and he cannot but be at once struck with the cumbrous, coarse, and complex character of the instruments, when compared with those now in use, which are intended to accomplish the same objects. A remarkable illustration offers itself in the formidable array of tools which were employed in the operation of trepanning. But further inquiry will also show that, in consequence of the improvement of the healing art, many instruments may become altogether useless. What surgeon would think of having recourse to the terrible cauterizing irons, formerly in use for the purpose of searing the palpitating stump after amputation, and of preventing the otherwise inevitable death of the patient by bleeding? This barbarous method, which rendered the operation dangerous, and the healing of the wound tedious, was, as is well known, happily rendered unnecessary by the celebrated Ambrose Paré, who adopted the simple expedient of tying the bleeding end of the divided artery.

In the above instance, the cauterizing irons, as far at least as dependence on their use in arresting hemorrhage was concerned, were banished for ever from the equipment of the surgeon. But if amputation, in this case, was robbed of the greater part of its terrors and dangers, so great a step in the amelioration of operative surgery might not unnaturally beget a hope that, by the advance of surgical science, in consequence of a better knowledge and clearer insight into the laws of the animal economy, the operation of amputation itself might be dispensed with, or limited to the fewest possible emergencies. Would that it were so, at least in all the diseases under which it is still unavoidably adopted; but in one instance, at all events, the genius of John Hunter has enabled surgeons to discard it, and to supersede its employment by a process at once simple, effectual, and almost void of suffering. In the disease called aneurism, produced by the yielding, at some point, of the coats of an arterial trunk, until it bursts externally, and the patient dies of loss of blood, Hunter taught surgeons, instead of depriving the patient of a limb, as had been most commonly heretofore done, to cure the disease by applying a ligature to the artery feeding the aneurismal sac, and thereby arresting the flow of blood, which contributed to the increase of the disease. It seems, however, probable, from recent cases, that even

this mild plan of treatment may be superseded, in many cases, by the simpler method of a merely graduated compression on the exterior of the limb.

It might seem, then, that the skill of the instrument-maker is destined to be less and less required in the progress of the healing art; but if his ingenuity may be thus balked of its fruit, sometimes it would appear to be evoked by the very improvements which are the pledge of the advance of surgery. A remarkable instance in point is the comparatively recent operation of lithotomy, the principal merit of which will be cheerfully accorded to the French surgeons. The only method of effectually relieving a sufferer from the torture and health-destroying consequence of stone in the bladder had been by cutting into the part, and by extracting the stone through the wound, which, in such cases, extends deeply, and involves parts which it would be dangerous, or even fatal, to injure. But by the novel process entitled lithotomy, instruments, ingeniously contrived for the purpose, are introduced into the bladder, and, in the hands of a skilful operator, are made to break, crush, and pulverize the stone, without the necessity of any incisions, and without those dangers to the patient which attended the operation of lithotomy. Here the aid of the mechanist was called in to contribute to the success of one of the greatest triumphs of modern operative surgery; and though the various modifications of the apparatus may have been suggested by surgeons, it may be safely said that the instruments would not have reached the perfection they have attained, as shown in the present Exhibition, without the skill and ingenuity of the instrument-maker. It should be remembered also, in connection with this subject, that Sir Astley Cooper devised a plan of extracting stones from the bladder whole and entire, when of small size, and that it was successfully carried out by means of an instrument constructed by the late Mr. Weiss, who will ever be regarded more as an artist than as a mere artificer, in the line in which he earned his deservedly high reputation.

If, then, the improvements in the apparatus and instruments of surgeons, during the last half-century, be considered in the spirit here vindicated, they will be found to depend on simplification, and if on novel appliances, yet on inventions, which have afforded new means of relief to the sufferer, or have tended to introduce the gentler and less formidable methods of operation, which are ever the characteristic of the enlargement of surgical knowledge. Among these, besides the capital instances adduced of modes of instrumentation of proved efficacy for relieving the sufferings of stone in the bladder, there may be mentioned—the stethoscope, invented by the celebrated Laennec, for aiding the ear in examining the morbid sounds of the chest, and which is not without its use to the surgeon; the stomach-pump, the valuable auxiliary in the treatment of poisons; Weiss's dilator of the female urethra, for the purpose of facilitating the extraction of foreign bodies from the bladder; the water-bed of Dr. Arnott, calculated, in all cases, to afford equal pressure in lying, and to prevent or remove the suffering and danger of bed-sores; various apparatus for facilitating and improving the treatment of fractures, especially the bed invented by Mr. Harrold for fractures of the spine, and the useful appliance of the gummed roller; the instruments for the cure of aneurism, by the graduated compression of the artery leading to the sac; the mechanical contrivances in aid of orthopædic processes; and the different forms to which caoutchouc has been made available in air and water-cushions, and in a variety of bandages and similar surgical appliances.

With these premonitions the Jury now proceed to give a brief synopsis of the contents of the present Exhibition.

#### *Instruments deserving notice.*

In looking over the assortment of instruments, which display not only all the ordinary contrivances required by the surgeon, but many novelties and ingenious adaptations and combinations, we may notice—in the instruments for operations on the eye—specula, knives, needles, scissors, hooks, which are admirably calculated for the delicacy of the requisite manipulations. In those for operations on

the ear, some novelties for the exploration of the meatus auditorius and Eustachian tube, and for the removal of polypi and foreign bodies from the external passage; an instrument for perforating the membrana tympani; and we may add to these a variety of acoustic contrivances for aids to imperfect hearing, many of which are so contrived as to be disguised as articles of furniture or personal attire. In those for operations on the nose, mouth, and pharynx, some modifications of the forceps for the extraction of polypi; syringes for injecting the nares and antrum; a variety of tonsillar guilloines; staphylophoric instruments, and new aids to dental surgery, especially Gilbert's chair, with a fulcrum, and instruments adapted to the forms of the several kinds of teeth, for their more easy extraction. In those for operations on the air-passages and thorax, various instruments for tracheotomy, and amongst them a novel tracheotome, and a valvular canula. We may include with these various forms of inhalers for the administration of medicinal vapours, stethoscopes of novel construction, and instruments for measuring the capacity of the chest, amongst which will be found Dr. Hutchinson's spirometer, Coxeter's portable spirometer, and Quain's stethometer. In those for operations, or other surgical ministrations, on the abdominal walls or alimentary canal, we may mention some improvements in the gullet forceps and in œsophageal tubes; modifications of the stomach-pump, which are calculated to facilitate its use; enema fountains; specula of different kinds for the examination of the rectum, or subservient to operations on the part; and a large assortment of trusses and herniary bandages, including most of those in use, and others of novel construction, especially such as those by which the wearer can vary at pleasure the force of the spring and the direction of the pad.

In those for operations on the genito-urinary system in the male, we find all the recent modifications of the instruments for lithotomy; lithotrites, of various novelty, including contrivances for the use of the screw and lever, as mechanical forces for breaking calculi, and one instrument for the purpose of pulverizing calculous fragments; syringes for injecting the bladder, together with contrivances for maintaining a double current of the injected fluid; dilators and various instruments to remove calculi from the bladder and urethra without cutting; trocars for puncturing the bladder, together with a form of canula so contrived as to prevent its slipping from the opening in which it is intended to remain; and, lastly, varieties of bougies, catheters, sounds, and instruments for applying caustic and for dividing strictures; and we may here notice the invention, patented by Charrière, of flexible ivory, as a novel material in their make. We may also draw attention to the speculum and lamp of Mr. AVERY (No. 631A, p. 478) for exploring the urethra and other lengthened canals; and the same gentleman exhibits a new instrument for lithotomy.

In those for operations on the genito-urinary system in the female, we have a large assortment of specula, dilators, syringes, forceps for removing polypi, instruments for applying ligatures, pessaries, and artificial supports of various kinds; an instrument for the cure of vesico-vaginal fistula; and different instruments for obstetrical purposes.

In those for operations on the extremities, we find, in connexion with some varieties in the knives and saws used for amputations, several noticeable modifications in the form and adaptation of tourniquets;—for the adjustment and co-adaptation of fractures, numerous contrivances claim attention in the way of fracture-beds, inclined planes, splints of various form and materials, a cradle with a moveable sling to enable the patient to sit up in bed, an apparatus for a fractured clavicle, together with pads and bandages in different materials;—for the reduction of dislocations several contrivances, in one of which the extending force is produced by a lever, and a neat apparatus for the reduction of the thumb or other small extremity.

In those for operations on the osseous system, the osteotomes claim attention, especially the revolving saw of HENNE, the circular saw of MACHELL, and, in addition to various instruments for the resection of bone, one will be

found for dividing and extracting lengthened sequestra. We noticed also a trephine-crown, which is made capable of expanding and contracting.

In those for operations on the vascular system, we find some variations of the scarificators for cupping, improved leech-tubes, and artificial leeches;—for the control of hæmorrhage, new forms of tourniquet;—instruments for transfusion;—for aneurism, various instruments for holding needles and applying ligatures, and instruments subservient to the new method of cure by graduated compression;—and for varices, elastic stockings and bandages.

Besides all these praiseworthy attempts to improve and extend the ministrations of the surgeon, we observe that great attention has been paid to *orthopædic processes* for the removal of deformities produced by weakness, misgrowth, or habitual position, in the form of spinal supports, corsets, chairs, and a system of machines exhibited by Mr. Caplin for combining gymnastic exercises with orthopædic objects.

In the *mechanical compensation of lost parts* great success has been obtained, as will be seen in examining the assortment of artificial eyes, noses, palate, teeth, arms, and legs. Among the arms, the apparatus and tools contrived by Major LITTLE to meet the loss of the right hand, is well worthy of inspection; and among the contrivances for supplying the loss of the lower limb, the admirable mechanism of Mr. B. F. PALMER'S artificial leg (United States, No. 39, p. 1435) deserves particular notice.

In addition to the above list, the Jury may be permitted to draw attention to CHAPMAN'S invalid couch (No. 601c, p. 476), Dr. VETTER'S invention, "denominated the medico-chirurgical ambulance" (No. 6, p. 407); and GOWING'S instruments of veterinary surgery (p. 475\*).

The Jury cannot, indeed, pretend to have noticed in this report every article worthy of the surgeon's attention, or to have mentioned all the names of exhibitors whose merits deserve a permanent record. This remark applies, perhaps, in the greatest degree, to the exhibitors of collections of instruments, several of which, such as those of CHAMBERLÈRE (No. 1145, p. 1233), COXETER (No. 482, p. 469\*), EVANS (No. 274, p. 38), FERGUSON (No. 638, pp. 477, 478), LUER (No. 1333, p. 1240), PHILP and WHICKER (No. 641, p. 465\*), SIMPSON (No. 642, p. 465\*), and WEISS (No. 631A, p. 478), form a complete and instructive epitome of the instrument-maker's art.

In concluding this account of the surgical instruments contained in the Exhibition, the Jury have to acknowledge the valuable assistance they have derived from Mr. PHILP; and to regret that, in consequence of his office as Juror, the house of PHILP and WHICKER (No. 641, p. 465\*) have renounced all competition in the award of prizes. The Jury deem it, however, no more than just to remark that the house of SAVIGNY, of which Messrs. PHILP and WHICKER are the representatives, embraces the history of the manufactory of surgical instruments in this country for a period of scarcely less than two centuries; and that the late Mr. Savigny, as is shown by his well-known work on the subject, was in his day almost the sole improver of instruments, which up to that time had been of a very rude construction. They desire to add that Mr. Philp has been practically engaged during the last fifty years in the manufacture of the justly-prized instruments, for which Savigny's firm has been celebrated, and that on the present occasion Messrs. PHILP and WHICKER, in the complete and excellent collection of instruments which they exhibit, have efficiently sustained the high reputation of their long-established house.

Thus in the Great Exhibition will be found the complete armoury and equipment of a surgeon, comprising a choice assortment of all the instrumental aids, in their most perfect form and finish, with which the ingenuity of the artist or artificer can furnish the operator or the

patient, for the relief of the manifold ills of suffering humanity,—as far, at least, as their remedy depends upon mechanical skill and contrivance. To attempt any critical examination of this admirable collection would be, however, in the opinion of the Jury, as hopeless as it would be invidious. The Jury appointed to report on surgical instruments could not, consistently with the objects and limits of this Report, enter upon the discussion of subjects which involve references to a large portion of the surgical records and literature of the last half-century; and they have no wish to make their Report the vehicle of advertisement, or to render it the occasion of controversy. They do not arrogate to themselves any judicial authority to decide on the claims of inventors, or on the comparative merits of improvers. They have endeavoured conscientiously, as far as their means of judgment have extended, to award prizes in those cases in which the objects exhibited display inventive talent, useful ingenuity, or superior mechanical skill; and if in some instances they may have left talent unrewarded, either from the imperfection of their judgment, or from the impossibility of acknowledging every degree of merit, they desire to record most unequivocally their sense of the general excellence manifested both in the contrivance and execution of the surgical instruments exhibited.

To the same Jury has been intrusted the duty of examining and reporting on the models of anatomy. Of these some beautiful examples have been exhibited by AUZOUX (No. 13, p. 1170), SIMPSON (No. 641, p. 465\*), TOWNE (No. 625, p. 477), and GORDON (No. 639, p. 465\*). The opinion which the Jury entertains of their merits they have expressed, by awarding to each of these contributors the Prize Medal. And whilst saying that such models are admirably calculated to aid the teacher in his demonstrations, the Jury, without detracting from their merit, may be permitted to observe that, especially in respect of human anatomy, they can never supply the place of actual dissection. They cannot, however, omit this opportunity of recording their approbation of the value of the labours of M. Auzoux, who, in respect of the durability of the material he employs, and of the scientific exactness of the structures he displays in the anatomy of man, and in that of various well-chosen examples of animals, both vertebrate and invertebrate, has earned the gratitude of teachers of anatomy and zoology. And they desire especially to express their admiration of the series of models in wax, which display the anatomy of the torpedo, not only as highly-interesting specimens of Florentine art, but as patterns of scientific accuracy and artistic beauty.

Finally, in accordance with the philanthropic designs of His Royal Highness the Prince Albert, and of those who have promoted, under the Royal sanction, this great national undertaking, the Jury beg to express their sincere wish that the department of the Great Exhibition, on which they report, may contribute to produce that interchange of knowledge and of amity which this assemblage from all parts of the world is calculated to foster, and which it is alike the interest and the duty of all nations, as integral parts of the human family, to cherish and to cultivate.

In making the following awards, the Jury intrusted with this delicate and difficult duty, desire to say, that in conformity with the directions of the Royal Commissioners, and without the means of marking degrees of merit, they have been under the necessity of avoiding a regard to comparative excellence. Also, that as they do not intend it to be understood, that others than those included in the prize list might not have properly received some testimonial of merit, so they trust, that the Exhibitors distinguished by the recommendation of the Jury will severally accept the prize awarded to them, not as a measure of their merit, but as a tribute to the excellence of the objects they exhibit.

## PRIZE MEDALS.

| NATION.        | Number in Catalogue. | NAME OF EXHIBITOR.       | Objects rewarded.   |
|----------------|----------------------|--------------------------|---|
| United Kingdom | 619                  | Afnott, J., M.D.         | A novel mode of applying cold as a therapeutical agent.   |
| France         | 13                   | Auzoux, Dr. L.           | The excellence of his anatomical models, admirably calculated to promote and aid the study of anatomy, human and comparative.   |
| United Kingdom | 631A                 | Avery, John              | An illuminating apparatus, designed to explore long and narrow canals, especially the male urethra.   |
|                | 676                  | Bigg, H., and Son        | Surgical instruments, excellent both in materials and workmanship.  |
| France         | 79                   | Burat Brothers           | Improvements in the construction of herniary bandages.  |
| Tuscany        | 85                   | Calami, Professor L.     | A series of models in wax, representing the anatomy of the torpedo in the most exact and beautiful manner.  |
| United Kingdom | 570                  | Caplin, I.               | Various kinds of apparatus, orthopaedic and gymnastic, especially those the value of which consists in removing the weight of the trunk, and at the same time increasing muscular strength by exercise.               |
|                | 570A                 | Caplin, Madame           | Corsets, ingeniously adapted for giving support to the trunk without confinement of the thorax.   |
| France         | 1145                 | Charrière, J. F.         | Instruments of various kinds, exhibiting novelty, inventive and adaptive ingenuity, and great perfection of mechanical execution.   |
| United Kingdom | 682                  | Coxeter, J.              | Surgical instruments, excellent both in materials and workmanship.  |
|                | 643A                 | Evans and Co.            | Surgical instruments, excellent both in materials and workmanship.  |
|                | 274A                 | Evans, W.                | An artificial leg, the peculiar excellence of which consists in giving a firm bearing on the stirrup in riding.   |
|                | 631                  | Ferguson and Sons        | Surgical instruments, excellent both in materials and workmanship.  |
|                | 639                  | Gordon, J.               | An anatomical model of a human figure in ivory, exhibiting the parts as they appear in dissection, and displaying an unwearied application of labour in the execution.  |
|                | 736                  | Gowing, T. W.            | Improvements in veterinary instruments.   |
|                | 565                  | Grossmith and Desjardins | Artificial eyes, remarkable for their close imitation of the natural appearance of these parts.   |
|                | 729                  | Hutchinson, Dr.          | His spirometer, an apparatus adapted to measure the quantity of air expired, in conformity with the proportion said to exist in healthy individuals, between the height of the stature and the capacity of the lungs. |
| Switzerland    | 106                  | Junod, T.                | An apparatus for hæmospasie, namely, for determining blood to large surfaces of the body, on the principle of dry cupping.  |
| France         | 1333                 | Lüer, A.                 | The general excellence of his instruments, and especially for the great ingenuity and admirable workmanship of several instruments for operations on the eye.   |
| United Kingdom | 654                  | Machell, T.              | A circular saw, intended to be used as an osteotome.  |
| United States  | 39                   | Palmer, B. F.            | An artificial leg, the contrivance of which combines lightness and a successful imitation of the motions of the joints.   |
| Portugal       | 633                  | Polycarpo, A.            | A case of surgical instruments.   |
| United Kingdom | 629                  | Rein, F. C.              | Acoustic instruments, ingeniously contrived for the aid of deaf persons, in a variety of highly convenient forms.   |
|                | 624                  | Simpson, G.              | An anatomical model of the human figure, consisting of pieces that may be combined and detached at pleasure, and calculated from its construction to bear the heat of tropical climates.                              |
|                | 642                  | Simpson, H.              | Surgical instruments, excellent both in materials and workmanship.  |
| France         | 1505                 | Thiers                   | An apparatus called Tétrelle, an ingenious contrivance for artificial lactation.  |
| United Kingdom | 625                  | Towne, J.                | His admirable models in wax, illustrating the process of incubation, and representing some parts of the human body as they appear in dissection.  |
|                | 631A                 | Wels and Son             | Instruments of various kinds, exhibiting novelty, inventive and adaptive ingenuity, and great perfection of mechanical execution.   |

Hadley, October 1851.

JOSEPH HENRY GREEN, REPORTER.

P.S.—Since the above Report has been in type, the attention of the Reporter has been drawn to "Photographic specimens of vaccine produced by inoculating the cow with the small-pox, showing the character of the vesicles in their different stages," exhibited by Mr. JOHN BADCOCK, of Brighton. The Reporter does not venture

to offer any opinion on the comparative value of such a mode of obtaining a fresh supply of vaccine matter; but he has great pleasure in having this opportunity of acknowledging the highly commendable zeal and public spirit of Mr. Badcock.

## CLASS XI.

### REPORT ON COTTON MANUFACTURES.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the  
OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

#### *Jury.*

Sir JAMES ANDERSON, Lord Provost of Glasgow, *Chairman*, Glasgow; Cotton Manufacturer.  
 PHILIPP ELLASSER, *Deputy Chairman*, Frankfurt-on-the-Maine; Merchant.  
 THOMAS ASHTON, *Reporters*, Hyde, near Manchester; Cotton Spinner.  
 C. BISCHLER, Austria; Vice-President of the Austrian Committee.  
 Col. R. E. COXE, United States; Planter.  
 W. GRAY, Mayor of Bolton, Wheatfield, Bolton; Cotton Spinner.  
 GEORGE JACKSON, Corporation Road, Carlisle; Cotton Spinner.  
 PAUL KIRCHMORER, Switzerland.  
 AUG. MIMMEL, France; President of General Council of Manufactures.  
 J. ASPINAL TURNER, Manchester; Cotton Spinner.

#### *Associates.*

THOMAS COATH, 7 Broad Street, Cheapside; linen and Manchester Merchant.  
 ROBERT JOHNSON, 95 Watling Street, City; War-houseman.  
 JOHN PITTMAN, 11 Bow Lane, Cheapside; Merchant.

#### COTTON YARN.

THE Jury appointed to examine cotton yarn and plain and coloured woven cotton cloths, have to report on yarn, that the specimens from England, Scotland, Switzerland, the Zollverein, France, and Austria, which they have considered it necessary to notice, are those manufactured by machinery. In the numbers of usual production and use (say from 6s. to 250s.), they have found it impossible to do more than report upon the general character of the specimens from the various countries, any superiority appearing to arise, not from greater skill in working, or superior mechanical appliances, but from the character of the cotton used.

Cheapness is the only other quality for which they could have made special mention; but they have found it impossible to arrive at any satisfactory results on this point, and have hence deemed it advisable to award no medals.

The yarns exhibited from England and Scotland are chiefly of second qualities, suitable for use in the trade, which supplies clothing to so large a portion of the working population of all parts of the world.

Swiss yarns, exhibited by eleven different spinners, are of very beautiful quality, and are adapted to the production of those cloths in which softness of texture and beauty of dye are required; great attention has been successfully paid to the selection and preparation of the cotton.

The specimens from France possess similar qualities, whilst those of the Zollverein are of various kinds; but are not in sufficient quantity to illustrate fully, the trade of the countries in that union.

In fine yarns, Messrs. T. HOULDSWORTH and Co., of Manchester (p. 482); Messrs. GARDNER and BAZLEY, of Manchester (p. 279); and M. MALLAT, of the firm of VANTROYEN and MALLAT, of Lille, in France (p. 1213), have each exhibited yarn of No. 600s.; in the first and last instances made into net and muslin, and in the second instance made into 9-cord sewing thread, believed to be the finest ever yet produced. Messrs. T. Houldsworth and Co. also exhibit small specimens of various degrees of fineness to 2150s., and Messrs. Gardner and Bazley to 2070s.; but it does not appear that they are produced in sufficient quantity to be of any utility.

Various specimens of yarns of hand-production are ex-

hibited from India—(curious on account of the shortness of the fibre of the cotton, and the fineness of the yarn produced), from Malta, and from Turkey. All these yarns have that peculiar excellence of softness and pliability never yet attained by machinery, but are very uneven and irregular in thickness.

#### DYED YARNS.

In dyed yarns, with the exception of the Turkey red shown by LIEHMANN BROTHERS, Mattwil, Switzerland, (p. 1274), the specimens exhibited by Great Britain, the Zollverein, Switzerland, Belgium, and Austria, do not merit especial mention; good Turkey red and other fancy colours being produced in each country.

#### THREAD, &c.

In thread there are few specimens exhibited from foreign countries.

#### CALICOS, &c.

In plain calicos the specimens of English manufacture show how successful the efforts to produce good articles of general utility have been. The colour and finish of the bleached goods are very superior.

It is, however, unfortunate that the manufacture, which forms a very large portion of both our export and home trade, should have been so imperfectly represented, that many of its most important varieties are entirely wanting in the Exhibition.

From the United States there is a good selection of drillings, grey sheetings, and jeans of excellent quality; and from Belgium and France a few specimens only of plain grey and white calicos, made, however, of cotton unusually fine for the purpose.

Specimens of white calico, prepared according to the patent of MERCER (p. 556), of Accrington, Lancashire, are exhibited, possessing the increased thickness resulting from this process; but as this invention is more important in dyed or printed goods, the Jury connected with that Class will report fully upon it. This Jury would, however, add, that, as far as the specimens enable them to judge, it promises to be a most valuable discovery when applied to bleached cotton cloth.

The Jury regret that no specimens of cords and beaver-teens were exhibited, or of the very important article of grey velvets or velveteens.

## MUSLINS, &amp;c.

Very good specimens of muslins (tarlatan, book, mull, lawn, &c.) are exhibited from Glasgow, Switzerland, and France, and of jaconot and cambric muslin from Manchester and Saxony. The British goods are suitable for the Indian and American, as well as the home markets. The plain muslins exhibited by native merchants of Dacca have great merit, especially when the rude mode of production is considered; but their cost is relatively high, and the finish universally defective; the yarn too is uneven, and frequently overtwisted.

In figured harness muslins, Scotland, Saxony, Switzerland, and France, exhibit articles of considerable beauty and utility, at comparatively low cost.

## COLOURED WOVEN COTTONS.

In ginghams, the large exhibition from Glasgow, Carlisle, France, Switzerland, the Zollverein, and Belgium, shows that the manufacture of these useful articles has received great attention, and attained great perfection in all those countries.

An interesting collection of woven checked goods is exhibited from India and the Archipelago, many of them being the originals from which the European manufactures (now much superior) have been copied.

In the class of goods submitted to their inspection, although many of them are of very great excellence, and evince the application of great skill, taste, and industry in their production, the Jury have found nothing possessing the pre-eminent merit which would induce them to recommend the award of a Council Medal. In the performance of their duties they have endeavoured to avoid making any invidious distinctions, or using any expressions which might tend to injure the interests or the feelings of the exhibitors.

The Jury award Prize Medals to the following Exhibitors:—

AMOSKEAG MANUFACTURING COMPANY, New Hampshire, United States (2, United States, p. 1433), for a very good assortment of drillings, tickings, sheetings, and cotton flannel.

ANDEREGG, TOBIE, Wattwyl, Switzerland (111, Switzerland, p. 1293), for cambric muslin made of unusually fine yarn.

ANDERSON, D. and J., Glasgow (16, Class XI., p. 481), for a good general assortment of ginghams.

BROOK, JONAS, and BROTHERS, Huddersfield (24, Class XI., p. 481), for their 2 to 9-cord thread, for its superior smoothness, strength, and freedom from fibre.

CHRISTY and SONS, Fairfield, near Manchester (44, Class XI., p. 481-82), for their improved manufacture of the Turkish bath towel.

DAUDVILLE, ALPHONSE, St. Quentin, France (156, France, p. 1178), for excellence of manufacture in harness window curtains and in harness piece muslins.

DE RAST, CAMILLE, Ghent, Belgium (189, Belgium, p. 1157), for beautiful grey calicos made of very fine cotton.

DUBAR, DELESPAUL, Roubaix, France (148, France, p. 1178), for cotton trouserings of excellent taste and quality.

DURANTON, J. B., Paris (494, France, p. 1201), for shirt fronts, produced by the loom in imitation of needlework.

FERR, J. C., St. Gall, Switzerland (122, Switzerland, p. 1274), for coloured Jacquard mus. n.

FEROUILLE and ROLLAND, Paris (500, France, p. 1183), for novelty of design and beauty of manufacture in coloured figured muslins.

FINLAYSON, F., and Co., Glasgow (8, Class XI., p. 480), for beauty of design and superiority of execution in fast-coloured sprigged lappets.

GARDNER and BAZLEY, Manchester (53, Class XI., p. 482), for fine yarns.

HARTMANN and SON, Munster, France (256, France, p. 1189), for brilliant, or figured cottons, of excellent make and assortment.

HORROCKS, MILLER, and Co., Preston (60, Class XI., p. 482), for the superior make and bleach of their shirtings and long cloths.

HOULDSWORTH, T., and Co., Manchester (54, Class XI., p. 482), for fine yarns.

JOHNSON, JABEZ, Manchester (48, Class XI., p. 482), for coloured quiltings and toilet covers, of excellent manufacture.

JOURDAIN, X., Altkirch, France (1631, France, p. 1255), for muslin made by power of 190s. warp and 250s. weft.

LAMBERTS, A. CHRIST., SON, Gladback (604, Prussia, p. 1084), for cotton kalmucks and beavers, as an improved manufacture of general utility.

LANG, J., Vienna (185, Austria, p. 1017), for ginghams, the quality and design of which are suited to French and German taste.

LEUMANN, BROTHERS, Mattwiel, in Switzerland (130, Switzerland, p. 1274), for specimens of Turkey red, of great brilliancy and force of colour. The award is made irrespective of the cost of this yarn.

LISBON WEAVING COMPANY, Portugal (707 to 712, Portugal, p. 1315), for specimens of blankets and shawls of cotton, a manufacture apparently peculiar to that country.

M'BRIDE and Co., Glasgow (6, Class XI., p. 480), for cotton diaper for table cloths and towelling woven by power.

MATR, J., SON, and Co., Glasgow (59, Class XI., p. 482), for beauty of design and execution in window-curtains, produced at a reduced cost by a new arrangement of the Jacquard loom.

MAJOR and GILL, Manchester (49, Class XI., p. 482), for double coutils and nankeens for corsets produced in the loom.

MAILLET, —, of the firm of Vantroyen and Mallet, Lille, France (715, France, p. 1213), for fine yarns.

MARTIN, W. and SON, Bolton (37, Class XI., p. 481), for very superior furniture dimities.

MYERSCUGH, STEELE, and Co., Bolton (39, Class XI., p. 481), for excellence of design and workmanship in toilet quilts and bed covers.

NAEF, MATTHIAS, Niederuzwyl, Switzerland (131, Switzerland, p. 1274), for the brightness of colour and good assortment of levantines.

NEF, J. J., Herisan, Switzerland (198, Switzerland, p. 1279), for white spotted muslins.

OURSAMP, THE COMPANY OF, (Peigné Delacourt, Manager), France (379, France, p. 1195), for bleached madapolams, of excellent quality and superior roundness of thread.

OWTRAM, R., and Co., London (62, Class XI., p. 483), for figured and checked cambrics of very superior manufacture.

PANSA and HAUSCHILD, Chemnitz, Saxony (42, Saxony, p. 1106), for 4-thread knittings and good general assortment of other numbers of knitting cottons.

PATTERSON, JAMIESON, and Co., Glasgow (11, Class XI., p. 480), for imitation Madras handkerchiefs of fast colours.

RANSAUER AENLY, Herisan, Switzerland, for very perfect specimens of tarlatan and book muslin.

RASCHLE and Co., Wattwyl, Switzerland (168, Switzerland, p. 1277), for imitation Madras handkerchiefs, of fast colours; those with blue grounds being especially good.

SYMINGTON, H. H. and Co., Glasgow (14, Class XI., p. 480), for beauty and appropriateness of design and excellence of manufacture of harness window curtains.

TANNER and KOLLER, Herisan, Switzerland (206, Switzerland, p. 1279), for scarf, shawl, and dresses with flounces, produced by an improved adaptation of machinery, and for beauty of design. Medal awarded in Class XIX.

TRÜMER and TÖPFFER, Chemnitz, Saxony (90, Saxony, p. 1109), for two coloured cotton table-cloths, of good design.

TOLSON and SONS, Huddersfield (116, Classes XII. and XV., p. 490), for vestings of great beauty of design and superiority of manufacture. Medal awarded in Class XII.

VOGEL and CARNER, Germ. Saxony (711, Zollverein, p. 1089), for the cheapness and good quality of their levantines.

WEIGLE, J. J., Ludwigsburg (29, Wurtemberg, p. 1115), for very useful and good waistcoatings relatively to their cost.

WILLIMENTIC DUCK MANUFACTURING COMPANY, Connecticut, United States (352, United States, p. 1457), for a specimen of cotton sail-cloth of very superior strength and evenness.

The Jury make Honourable Mention of:—

CLARKE, J. P., Leicester (32, Class XI., p. 481), for the great taste and ingenuity shown in winding and making up the specimens exhibited by him.

And also of the following manufacturers for very good assortments of ginghams and striped and checked goods. These are all useful, being suited to various markets, and

all valuable as cheap productions; and the Jury have found little difference in their relative merits:—

BAENZIGER and Co., Ebnat (112, Switzerland, p. 1273-74).

BREITENSTEIN and Co., Zofingen (117, Switzerland, p. 1274).

DE CUYPER, J. F., St. Nicholas (192, Belgium, p. 1157).

DIXON, PETER, and SONS, Carlisle (19, Class XI., p. 481).

JANSEN and LÜHDORF (56, Bavaria, p. 1300).

LIENHARDT, F., Hof, Bavaria (43, Class XI., p. 1300).

LOWTHIAN and PARKER, Carlisle (22, Class XI., p. 481).

M'GIBBON, EDWARD, Carlisle (20, Class XI., p. 481).

PEARSON and Co., Carlisle (21, Class XI., p. 481).

THOMAS ASIITON, REPORTER.

June 1851.

## CLASS XII.

## REPORT ON WOOLLEN AND WORSTED MANUFACTURES.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

*Jury.*

Dr. VON HERRMANN, *Chairman*, Munich; Privy Councillor in Finance Department.  
 HENRY FORBES, J. P., *Deputy-Chairman*, Bradford; Merchant.  
 SAMUEL ADDINGTON, *Reporter*, 105 St. Martin's Lane; Woollen Merchant.  
 HENRY BRETT, Wood Street, Cheapside; Woollen Merchant.  
 C. C. CARL,\* Zollverein; Manufacturer.  
 JOHN COOPER, J. P., Leeds; Woollen Merchant and Manufacturer.  
 GEORGE LAWTON, Mecklehurst, near Ashton-under-Lyne; Flannel Manufacturer.  
 THOMAS MARLING, Stroud; Retired Manufacturer.  
 J. RANDOING, France; Member of Central Jury, &c.; Member of the Legislative Assembly of France.  
 LEON SAMOILOFF, Russia; President of the Council of Manufactures at Moscow.  
 P. SCHÜLLER,† Austria.  
 ARN. SIMONIS, Belgium; Merchant; President of the Chamber of Commerce, Verviers.

*Associates.*

JOHN BARNES, Leeds; Salesman.  
 JOSEPH BATESON, Leeds; Merchant.  
 THOMAS DEWHIRST, Bradford; Worsted Spinner.  
 BENJAMIN HARRISON, Bradford; Worsted Manufacturer.

HENRY JENNINS, Leeds; Merchant.  
 HENRY KEMMALL, Rochdale; Flannel Manufacturer.  
 DAVID LUTTON, Leeds; Woollen Merchant.  
 EMILUS PRITLER, Bradford; Merchant.  
 GEORGE TETLEY, Bradford; Merchant.

\* F. LUCIUS, Proxy for M. CARL.

† C. OTTERMANN, Proxy for M. SCHÜLLER.

THE Jury appointed to decide on the merits of the various examples of Woollen and Worsted Fabrics, found it requisite to divide their duties, and to constitute four Sub-Juries for the consideration of the several subjects demanding their attention; the Report will therefore be found to present four general heads, viz., Woollen Cloths; Flannels and Blankets; Worsted and Mixed Fabrics; and Yarns.

In the course of their labours, the Jury were compelled to call in much additional assistance, and they have to acknowledge the valuable aid afforded them by the several Associate Jurors in simplifying duties of no ordinary character, since the great mass of articles coming under their cognizance rendered those duties as onerous as the responsibility was serious, owing to the great similarity and equality of merit displayed in almost every department.

In presenting their awards without recommending one Council Medal, the Jury consider it only due to the important branches of industry represented in Class XII., to state their conviction that in no point can they consider them as unworthy of the highest recognition which the Jury had the power to give or recommend; but feeling, from the great amount of merit displayed, that the recommendation of a Council Medal "for excellence of manufacture, beauty of design, or progress" in any one instance, would have involved the same recommendation in so many others, as utterly to destroy the value of that award, besides creating those invidious distinctions which the recognition of various degrees of the same kind of merit must suggest, the Jury determined to equalize such acknowledgments of excellence by awarding the Prize Medal only; leaving to the public, as the best arbitrators, the decisions on question of relative degrees.

## WOOLLEN CLOTHS.

Before proceeding to report upon the articles contributed by the several Exhibitors, the Jury consider it desirable to give some short account of certain differences of manufacturing treatment between our home productions and those of the Continent.

In ENGLAND a new era for this trade may be said to have commenced, in the year 1824, by the introduction of

what is called the *roll-boiling process*, which produces a permanent lustre on the face of the cloth, that neither spots by rain, nor is removed by damp. This process was introduced by Messrs. Daniell and Wilkins, of Twerton, near Bath, who took out a patent for it in the above year. The permanent face is imparted by rolling the cloth, before being racked or tenterd, round a cylinder, not very tightly, and putting it in sealding water for two or three hours, then taking it out and letting it cool: this has to be done several times during the process of dressing. About the same period great improvements were made in the milling and weaving departments, which enabled the cloth to bear this severe test. Other manufacturers had to pay a premium to the above-named firm for three years, when the patent was disputed, and ultimately lost through the evidence of a Yorkshire manufacturer, who proved that he had used it several years before; but, owing to his connection being very limited, it did not answer his purpose to continue it. However, the credit must remain to Messrs. Daniell and Co. for the perfection and general introduction of a plan which has since been universally acted upon.

Up to this time the general plan had been to dye blacks in the piece, of a common dye; but this new method was found to interfere with that of dyeing, from its being found difficult to make the dye penetrate through the improved fabric; this led to the gradual introduction of dyeing in the wool of a permanent kind,—a process which, in its execution, requires considerable skill and experience, but which is now so perfected as to leave little or nothing to be desired. While speaking of the improvement in woollen manufacture, it is but justice to mention the introduction, by Messrs. Daniell and Wilkins, of a new method of weaving stout beaver cloth for winter wear, called the "patent double cloth," which was patented by them in 1838, the material possessing considerable merit for its soft pliable character, united with great durability, causing it to entirely supersede the old *milled cloth*, which was hard and uncomfortable. By this mode of weaving a coarse and warm material is obtained on one side, and on the other the very finest cloth; an important consideration in olden times, when railway travelling was unknown, and the requirement more felt.

This kind of cloth has a good sale, and is much sought after by foreigners, who require the stouter kind of fabrics.

The continental methods of producing a permanent face are totally different, much shorter in their processes than our's, and performed at a much cheaper rate. Their methods are,—the one by rolling the cloth tightly round a hollow perforated cylinder, into which the steam is introduced to produce the desired effect; the other, and more general one, by folding the cloth and putting it under very powerful pressure, then allowing steam to penetrate the whole bulk. Both these methods cause a hardness, which is observable in all the continental productions, and would be more so if applied to stouter fabrics. There are also to be seen, on cloths that have been so treated, marks of the folds, which cannot be effaced by any ordinary means. Several houses in Leeds have tried this plan, but found that the fold-mark and hardness of the fabrics formed obstacles to their sale in the home market, though not for exportation; consequently it has been adopted to meet the competition abroad.

Considerable attention has been given to the dyeing of cloth in the different countries; especially the finer fabrics, which are all equally well and permanently dyed. In the middle qualities some are permanently dyed and others not; this is the case in all countries, and in the lower qualities (with some few exceptions) they are all of a common dye. This is a circumstance easily accounted for by the cost of the permanent dye being considerably more, and from its detracting slightly from the appearance and feel of the fabric; facts which must be admitted are great impediments in these competitive times, although there can be no doubt that real and ultimate economy must remain with a permanently dyed article.

We shall now proceed to enumerate the different seats of manufactures from which this department of the Exhibition has been supplied.

The woollen manufactures of the West Riding of Yorkshire, and those of the West of England, were established in the reign of Edward the Third, in the year 1336; and from that period to the present time, the principal woollen trade of Great Britain has been located in these two important districts.

Leeds is the most important town in England for the extent and variety of its manufactures in wool, and exhibits here a fair specimen of its productions; but its principal trade is in the middle and lower qualities, of which a large amount are exported.

The borough of Leeds, which, according to the census of the present year, contains a population of 171,805 inhabitants, and the populous small towns and villages around it, are occupied, to a large extent, in the manufacture of woollens. This district has contributed to the Exhibition an extensive assortment of woollen cloths in fine, middle, and low qualities, cloakings, beavers, mohairs, cashmerettes, tweeds, and pilots, which, for appearance and cheapness, maintain the high position for which it has been so long in repute. Lately the manufacture of doeskins and cashmeres has been partially and successfully introduced, and some good specimens of these goods have been exhibited. The merchants and manufacturers engaged in the woollen trade of this important district supply, very extensively, the home, foreign, and colonial markets; and adapt the fabrics manufactured to the peculiar taste of each.

Much attention has, of late, been devoted to perfecting the woollen manufacture in all its branches. It is probable that the opportunity afforded to our local manufacturers of seeing the various productions of other nations in the Great Exhibition, will materially assist in effecting this object.

Huddersfield, with its neighbourhood, is the second place in importance for the quantity and great variety of woollen cloths which it produces. Here, an immense portion of the fancy trouserings are made, besides broad-cloths; but the productions of this town are principally for home consumption, and of the middle and lower qualities. This town, in 1820, made goods from home-grown wool only, but since that period it has gradually

risen into great importance. The manufacturers of this neighbourhood exhibit a great variety of fabrics which fairly represent their products; among these may be noticed a number of double-faced cloths, presenting a different colour on each side, which have attracted considerable attention; but this idea is evidently taken from Daniell and Co.'s patent; and although interesting, these double-sided cloths of different colours appear to be more ornamental than generally useful as an article for clothing.

**WEST OF ENGLAND.**—Stroud, or Stroudwater, Gloucestershire, is so called for the purity of its water, which have been in repute for dyeing scarlets and light dyes for centuries. This town and neighbourhood, with Ebley Eastington, Stonehouse, and Minchinhampton, are the great seats of manufacture in the West, principally for fine broad-cloths. They exhibit a great variety, in colours of the finest character and permanent dye, but few in regard to quality, arising principally from their not precisely comprehending the exact object of the Exhibition, which they imagined to be for the display of goods of a pre-eminent character, rather than for variety of production.

Trowbridge, Wiltshire, is the next town and neighbourhood of importance in the West, exhibiting principally narrow or trouser goods of the finest quality and permanent dye.

Chippenham, Melksham, and Bradford, Wilts, also exhibit a variety of very choice and fine permanent dye, in black and coloured cloths.

Frome, Somersetshire, and Twerton, near Bath, exhibit likewise some beautiful specimens of cloths, beaver, and Venetians.

**SCOTLAND.**—Glasghields, Aberdeen, Selkirk, Hawick, and other places exhibit a great variety of fabrics in trouser goods, of a beautiful soft character and permanent dye.

**IRELAND.**—Mr. J. REID, of Dublin, exhibits a good variety of frieses, and tweeds of considerable merit, particularly deserving of encouragement, as a fair specimen of the products of that country.

**FRANCE.** The principal seats of this manufacture in France are Sedan and Elbeuf:—Sedan, of blacks, broads, and narrows. Sedan exhibits a choice and beautiful thin fabric in these articles, all dyed in the piece, but beautiful of their kind. Elbeuf shows a great and beautiful variety of fancy doeskins and cloakings of great taste. Abbeville, Laeviers, and Vire, also contribute a number of woollen articles of considerable merit.

**BRITAIN.**—Verviers and its neighbourhood are the principal seat of manufactures for woollens in this country. The value of manufactured goods is about one million sterling per annum (population 24,000), the markets for which are the interior of the country, Holland, Switzerland, Italy, and America. The manufacturers of this country exhibit a small quantity, but a nice assortment of very choice piece-dyed blacks and satin cloths of a thin fabric.

**ZOLLVEREIN.**—The Zollverein, including Saxony, exhibit an immense quantity of woollen goods, from a great number of places and manufactories; chiefly of the middle and lower qualities, though several are of a fine character, all very well manufactured and of considerable merit. The chief market for these goods is America.

**AUSTRIA.**—Brunn is the chief seat of manufacture in this country. The products exhibited are without any face, or are of what we should call the "old make;" but this appears to be the fashion in Vienna: in other respects they are of a good character. Reichenberg, in Bohemia, also exhibits a variety of middle and lower qualities of considerable merit, dressed after the German plan.

**RUSSIA** exhibits a small quantity of woollen fabrics of good character, prepared after the German plan; and being of a stout make, they exemplify what the Jury previously stated of the hardness produced by that method.

**SPAIN** has sent a small variety of woollens; some of these made of wool from their own sheep, others from the fleece of German sheep, which is much superior—a singular fact, as the Germans formerly imported their sheep from Spain.

AMERICA exhibits a small quantity of woollen goods of moderate pretensions.

SWITZERLAND sends a small and indifferent lot of woollen productions.

TURKEY forwards a small assortment, tolerably good for a first attempt.

HOLLAND contributes a few coarse woollens.

PORTUGAL exhibits a pretty good variety, but of very primitive character.

CANADA shows but few woollen goods.

SOUTH AUSTRALIA.—From Sydney are exhibited three pieces of 3-tweeds, manufactured by J. WALKER, which deserve great praise, as coming from a young colony, and certainly show that with a few such men, aided by capital and machinery, the colonies might soon be made to produce many of their absolute necessities of this description.

Three exhibitors and manufacturers of woollen cloths are members of this Jury, and are therefore not strictly within their cognizance, or eligible for any award. The Jury, however, desire to record their opinion of the goods exhibited by them. These exhibitors are:—

COOPER, D. and J., of Leeds. (42, Classes XII. and XV., p. 486.)

RANDONG, J., Abbeville, France. (No. 973, France, p. 1226.) The principal of one of the oldest establishments for the manufacture of woollen cloths in that country.

SIMONIS, E., Belgium (464, Belgium, p. 1166).—who presents a particularly beautiful assortment of piece-dyed blacks for exportation, of permanent dye and finish.

Each of these gentlemen would have been entitled to a Prize Medal for the excellence of his productions, had he not been a member of the Jury.

The Jury have carefully examined all the woollen goods in the Exhibition—a task which has been much prolonged by the non-attendance, in due time, of any Juror from the Zollverein, Russia, or Austria, to explain or give information as to prices. This was a source of great difficulty; but after a long and patient investigation, the Jury have come to the resolution to award Prize Medals to the following manufacturers and exhibitors:—

AKSENOFF, J., Klintz, Government of Tshernigoff. (182, Russia, p. 1372.) For excellence of manufacture and finish.

APPERLEY, J. and D., Stroud, for the fine specimens of black cloth exhibited by Messrs. BULL and WILSON, St. Martin's Lane (12, Classes XII. and XV., p. 486). The Jury conceive that the merit of the production is due to the manufacturer, and not to the exhibitor, and therefore award the Medal to Messrs. J. and D. APPERLEY, whose name appears on the cloth.

ARMITAGE BROTHERS, Manufacturers, Huddersfield. (103, Classes XII. and XV., p. 489.) For excellence of manufacture, combined with economy.

ASTORIAN COMPANY, Huddersfield. (276, Classes XII. and XV., p. 490. Exhibited through Lewis and Allenby.) For a variety of articles made of fur from the common hare.

BACOT, PAUL, & SONS, Sédan. (1062, France, p. 1229.) For excellence of manufacture in fancy black and satin doeskins, and fine piece-dyed black cloths of a thin make, of permanent dye and finish.

HARRICOT and HIRAT, Manufacturers, Huddersfield. (105, Classes XII. and XV., p. 489.) For great excellence of manufacture.

BEARDSSELL, ISAAC, and Co., Manufacturers, Thongbridge, near Huddersfield. (109, Classes XII. and XV., pp. 489, 490.) For excellence of manufacture, with great beauty of design.

BEARDSSELL, C., and Co., Manufacturers, Holmebridge. (120, Classes XII. and XV., p. 490.) For beauty of manufacture, with great taste.

BENNETT, J. and A., Bradley Mills, near Huddersfield. (95, Classes XII. and XV., p. 489.) For ingenuity in the application of new materials.

BERNHARD, W., Leisnig. (121, Saxony, p. 1110.) For general excellence of manufacture.

BERTHELE, CHESNON, and Co., Sédan. (1082, France, p. 1230.) For excellence of manufacture and beauty of design in fancy doeskins.

BIOLEY, F., and Son, Verviers. (195, Belgium, p. 1157.) For superior manufacture in piece-dyed blacks of a thin fabric for exportation, of permanent dye and finish.

BRAUN BROTHERS, Hersfeld, Hesse. (491, Prussia, p. 1079.) For excellence of manufacture.

BROOKE, JOHN, and SONS, Manufacturers, Honley, near Huddersfield. (86, Classes XII. and XV., p. 489.) For general excellence of manufacture, finish, and dye.

BROWN, J. and H., and Co., Manufacturers, Selkirk, Scotland. (469, Classes XII. and XV., p. 501.) For general excellence of manufacture.

CARR, T. and W., Manufacturers, Twerton, near Bath, Somersetshire. (273, Class XII. and XV., p. 499.) For excellence of manufacture in fine cloths of permanent dye and finish, with beavers of a superior quality and considerable novelty of production.

CHENNEVIERE, THEODORE, Elbœuf. (1559, France, p. 1251.) For extraordinary merit of manufacture and novelties of design, in great variety.

CLARK, J. and T., Manufacturers, Trowbridge, Wiltshire. (13, Classes XII. and XV., p. 486.) For excellence in manufacture, permanency of dye, and finish, in a variety of articles.

CROMBIE, JAMES, and Co., Manufacturers, Aberdeen. (228, Classes XII. and XV., p. 497.) For superior manufacture and beauty of design.

DAVIES, R. S., and SONS, Manufacturers, Stonehouse Mills, near Stroud. (214, Class XII. and XV., p. 496.) For excellence of manufacture in fine scarlets.

DICKSONS and LAING, Manufacturers, Hawick and Glasgow. (234, Classes XII. and XV., p. 497.) For superior manufacture and extraordinarily fine qualities.

DUNOIS, G., and Co., Verviers. (196, Belgium, p. 209.) For general excellence of manufacture in trouser goods.

EYRES, WILLIAM, and SONS, Leeds. (27, Classes XII. and XV., p. 487.) For excellence of manufacture, with economy.

FILDER, A. G., Upatovka, near Kalish. (351, Russia, p. 1383.) For excellence of manufacture and dye.

FORTIN-ROUTELIER, Beauvais. (484, France, p. 1201.) For beautiful production of felt cloths for pianofortes.

FÜRSTER, E., Grueneberg, Silesia. (220, Prussia, p. 1060.) For excellent manufacture of Spanish stripes.

GEISLER, C. S., Görlitz, Silesia. (100, Prussia, p. 1054.) For excellence of manufacture, and permanent dye and finish.

GEYERS and SCHMIDT, Görlitz. (50, Prussia, p. 1050.) For excellence of manufacture, dye, and finish.

GOTT and SONS, Manufacturers, Leeds. (47, Classes XII. and XV., pp. 487, 488.) For excellence of manufacture, in a great and beautiful variety of colours, for exportation.

GRAY, SAMUEL, Manufacturer, Calverly, Leeds. (67, Classes XII. and XV., p. 488.) For general excellence of manufacture.

GROSSMAN, C. G., Bischofswerda. (124, Saxony, p. 1110.) For excellence of manufacture, dye, and finish, for exportation.

HAAS, J. P., and SONS, Birtscheid. (357, Prussia, p. 1071.) For general excellence of manufacture.

HABERLAND, G. A., Finsterwalde. (99, Prussia, p. 1054.) For general excellence of manufacture.

HAGUES, COOKE, and WORMALD, Dewsbury. (25, Classes XII. and XV., p. 487.) For excellent production of Spanish stripes.

HARGREAVE and NUSSEY, Manufacturers, Farnley Low Mills. (28, Classes XII. and XV., p. 487.) For general excellence of manufacture, and great ingenuity in the application of new materials.

HELM, W., Manufacturer, New Mills, Stroud. (207, Classes XII. and XV., p. 496.) For very superior black doeskins, with a very great variety of cass and cashmeretts, in a variety of beautiful and delicate colours.

HENDRICH, FRANCIS, Eupen, near Aix-la-Chapelle. (367, Prussia, p. 1071.) For excellence of manufacture and finish.

HENRY, A. and S., and Co., Manufacturers, Leeds. (38, Classes XII. and XV., p. 487.) For excellence of manufacture, economy, and uniformity.

HERRMANN, W., Leisnig. (139, Saxony, p. 1110.) For general excellence of manufacture.

HOOPER, C., and Co., Manufacturers, Eastington Mills, near Stroud. (210, Classes XII. and XV., p. 496.) For superior merit in the manufacture of fine cloths of permanent dye and finish, and for great variety; also for a beautiful production of elastic cloths for gloving.

INGLIS and BROWN, Manufacturers, Galashiels. (191, Classes XII. and XV., p. 495.) For general excellence of manufacture and style.

ISAIEFF, P., of Klintzon, Government of Tshernigoff. (184, Russia, p. 1372.) For general excellence of manufacture.

ITZIGHOHN, MARCUS, Nendamm. (97, Prussia, p. 1054.) For excellence of manufacture in low-priced productions, combined with strength.

JUHEL-DESMARIS, J., Vire. (278, France, p. 1190.) For excellence of production, economy, and utility.

KESSELKAUF, J. H., Aix-la-Chapelle. (371, Prussia, p. 1071.) For excellence of manufacture and finish.

LENORMAND, A., Vire. (588, France, p. 1206.) For excellence of production, cheapness, and utility.

LOCKWOOD and KEIGHLEY, Manufacturers, Huddersfield. (104, Classes XII. and XV., p. 489.) For excellence of manufacture in woollen cords and velveteens.

LUTZE BROTHERS, Cottbus, Silesia. (103, Prussia, p. 1054.) For excellence of manufacture and of permanent dye and finish.

MAHLING, S. S., and Co., Manufacturers, Ebley Mills, Stroud. (209, Classes XII. and XV., p. 490.) For general excellence in manufacture and dye.

MEISSNER, F. T., Grossenhain. (129, Saxony, p. 1110.) For excellence of manufacture and finish, for exportation.

OFFERMANN, F. W., Muntzon, Ingenbruch. (350, Prussia, p. 1070.) For excellence of manufacture in fancy trouser goods.

PALLING, W., Manufacturer, Painswick. (213, Classes XII. and XV., p. 496.) For excellence of manufacture in billiard cloths and scarlet hunters' or milled cloths.

PARNUIT, DATTREMS, and Co., Elbœuf. (673, France, p. 1211.) For excellence of manufacture, design, and cheapness.

PAWSON, SON, and MARTIN, Manufacturers, Leeds. (40, Classes XII. and XV., p. 487.) For general excellence of manufacture, and permanent dye and finish.

PEILL and Co., Düren. (369, Prussia, p. 1071.) For general excellence of manufacture, dye, and finish.

PORCOCK and RAWLINGS, Chippenham, for a variety of very beautiful cloths—blacks, blues, and medleys—all of great merit of manufacture, permanence of dye, and finish, exhibited by Messrs. BARBER, HOWSE, and MEAD, St. Paul's Churchyard. (19, Classes XII. and XV., p. 487.)

The Jury, in awarding the Medal to the manufacturer instead of the exhibitor, do so upon the principle above stated. In this case, however, there are additional circumstances to guide the Jury in their award, as Messrs. Pocock and Rawlings' application for space had been overlooked; and when an allotment was made to them it came too late, as the cloths made for the Exhibition had been sold to Messrs. Barber, Howse, and Mead, for whom Messrs. Pocock and Rawlings had expressly manufactured other cloths included in the award.

REED, J., Dublin, for very fine specimens of frieze cloths and milled tweeds, exhibited by Mr. R. ALLEN, Sackville Street, Dublin. (259, Classes XII. and XV., p. 498.) The Jury award the Medal as an encouragement to this branch of manufacture in Ireland.

ROBERTS, W., and Co., Manufacturers, Galashiels. (480, Classes XII. and XV., p. 502.) For general excellence of manufacture and style.

SALTHER, SAMUEL, and Co., Manufacturers, Trowbridge, Wiltshire. (250, Classes XII. and XV., p. 498.) For excellence of manufacture, both as to quality and variety in fancy doeskins, and other trouser goods.

SCHÖLL, A., Brunn. (226, Austria, p. 1217.) For excellence of manufacture of stout goods for overcoats and trousers.

SCHÖLLER, L., & Sons, Düren. (374, Prussia, p. 1071.) For excellence of manufacture in fine cloths, of permanent dye and finish.

SCHÜRMANN and SCHRÖDER, Lennep. (496, Prussia, p. 1079.) For superiority of manufacture, dye, and finish.

SHAW, J. W. and H., Manufacturers, Victoria Mills, Huddersfield. (98, Classes XII. and XV., p. 489.) For excellence of manufacture and dye.

STEGMUND, W., Reichenberg. (230, Austria, p. 1018.) For general excellence of manufacture.

SIGNORET-ROCHAS, P., Vienne. (1013, France, p. 1227.) For economy of production.

SKELL, JOHN, Leeds. (24, Classes XII. and XV., p. 487.) This gentleman is not a manufacturer, but a finisher of cloth, and the award is for the beauty of finish only.

SPENGLER, KARL, Crimmitzschau. (117, Saxony, p. 1110.) For general excellence of manufacture.

STANCOMB, W. and J., junrs., Manufacturers, Trowbridge, Wiltshire. (17, Classes XII. and XV., p. 487.) For excellence of manufacture in a great variety of trouser goods.

SYKES D., and Co., Finishers, Leeds. (75, Classes XII. and XV., p. 488.) For beauty of finish.

SYKES, J. and SON, Leeds. (34, Classes XII. and XV., p. 487.) For uniformity of make and general excellence of finish.

THETVERIKOFF, —, near Moscow. (187, Russia, p. 1372.) For excellence of manufacture and finish.

THORNTON, FIRTH, RAMSDEN, and Co., Leeds. (32, Classes XII. and XV., p. 487.) For general excellence of manufacture, finish, and great variety of character.

TOLSON and SONS, Manufacturers, Dalton, Huddersfield. (116, Classes XII. and XV., p. 490.) For superiority of make and style in trouser goods.

VICTORIA FELT CLOTH COMPANY, Leeds. (327, Class XIX., p. 572.) For superior felt cloth for flooring or carpets. Medal awarded in Class XIX.

WALKER, JOSEPH, and SONS, Lindley, Huddersfield. (87, Classes XII. and XV., p. 489.) For excellence of manufacture and finish in frock cloths.

WALKER, J., and SONS, Manufacturers, Millshaw Mills, Leeds. (79, Classes XII. and XV., p. 488.) For excellence of manufacture and economy.

WILKINSON, JOHN, Inventor and Manufacturer, Leeds. (51, Classes XII. and XV., p. 488.) For felt cloths for ships' sheathing, and medical purposes, in great variety.

WRIGLEY, J. and T. C., and Co., Manufacturers, Huddersfield. (117, Classes XII. and XV., p. 490.) For general excellence of manufacture, and ingenuity in new application of materials.

YORK and SHEEPSHANKS, Manufacturers, Dyers, and Finishers, Leeds. (49, Classes XII. and XV., p. 488.) For general excellence of manufacture.

The Jury desire to make Honourable Mention of the following Exhibitors:—

GINZEL, B. C., of Reichenberg. (210, Austria, p. 1018.) For woollen cloths.

MORO BROTHERS, of Klagenfurt. (218, Austria, p. 1018.) for the beauty of their colours.

WALKER, J., of Sydney. (23, p. 487.) For three pieces of tweeds, of great merit for so young a colony.

#### WORSTED STUFF GOODS.

The term "Worsted Stuffs" is applied to fabrics made from combed wool, including those in which combed wool is combined with cotton and silk. These fabrics are thus distinguished from woollen cloths, in which the wool is not combed, but only carded, and which are subjected, also, to the process of "fulling." The wool used in the worsted trade is mainly of long staple; that used in the cloth trade is short. The worsted manufacture, although of very ancient date, has only attained its present eminence in England during the last quarter of a century. According to a generally-recognised tradition, the invention of the wool-comb is attributed to St. Blaise, and the day of his canonization, February 3, was, until very recently, kept in Bradford as the gala-day of the trade. The term "worsted" is said to have been derived from a village in Norfolk of that name, in which these goods were first produced in the reign of Edward III. by weavers brought from Flanders. The cruel persecutions

of the Duke of Alva, in 1570, drove over a large number of Flemish refugees, to whom both the woollen and the worsted trades were much indebted. Many settled in Yorkshire, especially at Halifax, which was, for many years, the principal seat of the manufacture, and has always maintained its superiority in the production of damasks, lastings, and other heavy goods. The inventions of the spinning-jenny, the mule, the throstle, and other machinery, in the latter half of the last century, were gradually extended from the cotton to the worsted trade. The first spinning machinery erected in Bradford was in 1790, when a few frames were set up in a private house. At this time the wool, after being combed, was carried into the villages to a considerable distance around, and there spun by the hand-wheel; a primitive method, which was gradually superseded by the spinning-frame. The first factory in Bradford was built in 1795; but it was not until thirty years afterwards that the power-loom was introduced, and considerably later before its use became general. From the year 1825, the worsted manufacture has made most rapid and unprecedented progress. Up to that period, and for some years afterwards, all the goods were made from wool alone;\* but about the year 1834, manufacturers of worsted weft and cotton warp were first brought forward, and gave a great impetus to the trade. This was still further increased by the introduction, in 1836, of the wool of the alpaca, an animal of the *Llama* tribe, inhabiting the mountain ranges of Peru. This wool is of various shades of black, white, grey, brown, &c., and is remarkable for brightness and lustre, great length of staple, and extreme softness. Considerable difficulties were at first experienced in the working of this material; but they were ultimately overcome, and the alpaca manufacture now ranks as a very important branch of the worsted trade. About the same time, or shortly afterwards, mohair, or goat's wool, from Asia Minor, was brought into general use in the West Riding of Yorkshire, and many beautiful fabrics were produced from it: silk, also, in combination with wool, alpaca, and mohair, has been largely used. Improved machinery has been devised; more rapid processes of manufacture adopted; and the results of all these improvements, and the introduction of these new materials have been—the opening of new branches of industry,—the quadrupling, within thirty years, the number of workpeople employed,—and the production of an immense variety of fabrics for the purposes of clothing and furniture.

The rapid progress of the trade may be illustrated by a reference to the town of Bradford, which is the centre of the manufacture, and the great market where its productions are disposed of. The population of the borough has increased in the following ratio, viz.,—

|                |         |
|----------------|---------|
| In 1801 it was | 13,264  |
| 1811    "    " | 16,012  |
| 1821    "    " | 26,309  |
| 1831    "    " | 43,527  |
| 1841    "    " | 66,718  |
| 1851    "    " | 103,782 |

At the beginning of the present century there were only three mills in Bradford; there are, now, upwards of 160.

The following returns will show the extent of its present manufacturing operation: they comprise the parish of Bradford, and the village of Bingley:—

|                                  |                     |
|----------------------------------|---------------------|
| Number of spindles               | 355,792             |
| Number of power-looms            | 17,294              |
| Moving power, steam              | 3,884 (horse power) |
| Do. water                        | 1134 do.            |
| Children employed under 13 years |                     |
| of age:—Males                    | 1,469               |
| Females                          | 1,729               |
| Males from 13 to 18              | 3,426               |
| Do. above 18                     | 5,951               |
| Females above 13                 | 21,280              |

Total persons employed:—Male 10,846  
Female 23,009

Total 33,855

\* We except of course bombazines and other articles manufactured in Norfolk, which come under the head of "Mixed Fabrics."

The following is a summary of the whole of the worsted factories in Great Britain and Ireland, nearly seven-eighths of which belong to the West Riding of Yorkshire.—See Table, p. 355.

The classification of worsted stuffs contained in the list drawn up for the Juries has reference to the materials of which they are composed; viz.,—

1. Fabrics composed entirely of wool.
2. Ditto of wool and cotton.
3. Ditto of wool and silk.
4. Ditto of wool, silk, and cotton.
5. Ditto of alpaca and mohair, mixed with cotton or silk.

The first of these divisions comprises the well-known fabrics called "merinos," double-twilled, so denominated from the Spanish wool of which they were first manufactured. In this article the French have always had an unquestionable superiority, and many of the specimens in the Exhibition fully maintain their reputation. There are some goods of this class, however, in the Bradford department, but little inferior to them. In single-twilled merinos, the worsted manufacturers of Yorkshire have, at all times, had the decided pre-eminence. Shalloons, serges, lastings, all stout and heavy articles, are manufactured chiefly at Halifax and at Keighley. Damask for curtains and hangings are also made at Halifax; and this branch of the trade has arrived at great perfection, both in excellence of material and elegance of design. Of the fabrics composed of wool and cotton, the articles denominated Cobourg and Orleans cloth,—the former being twilled and the latter plain,—have been staple manufactures, of which the consumption has been immense: they are made chiefly at Bradford and Keighley. Many of the silk warp and worsted weft fabrics are distinguished by their richness and durability. The alpaca and mohair manufactures (carried on at Bradford and Bingley) are remarkable for their softness and brilliancy, and the great variety of purposes to which they are applicable. The importation of alpaca wool has increased from 7,000 bales in 1836, to 20,000 bales in 1850; and of mohair, from 5,621 bales in 1841, to 12,884 bales in 1850. It is in the production of articles in which wool of various kinds is combined with cotton and silk, that the superiority of the British manufacturer is most apparent; no such goods being produced on the Continent in any extent, or of any great excellence. This result could not have been attained had not the skill and enterprise of the manufacturer been aided by that of the worsted dyer. The chemical processes required, in order that a fabric composed of both vegetable and animal substances may be made to receive an equal and regular dye, are necessarily varied and intricate; but so successful have been the efforts of the dyers, that goods made of white cotton warp and worsted weft, can be dyed quite as perfect in colour, as French merinos composed of wool alone.

The consumption of these various manufactures is immense. The looms are capable of producing upwards of 80,000 pieces per week, averaging 30 yards each. These goods are not only sold in the United Kingdom, but are largely exported, as the following returns will show, to the United States of America; and to Germany and other parts of the continent of Europe.

Exports, during the six months from the 1st of January to 28th June, 1851:—

|  |
|--|
| Woollen and worsted yarns, 5,567,854 lbs.    |
| Woolens and cottons, mixed (value) £830,478. |
| Stuffs, woollen, and worsted do. £1,896,228. |

All that is now wanting in the English worsted trade is, that the same enterprise should be exhibited, as heretofore, in the working-up of materials into new forms, combined with greater taste in the production of fancy goods.

The goods of this division, contained in the Exhibition, include a very large variety of fabrics used for ladies' and children's dresses, for furniture hangings, for coatings, and other purposes, made from wool, alpaca, and mohair, combed and spun, either alone or in combination with cotton, silk, &c. The Jury have carefully and minutely examined all the fabrics brought under their

SUMMARY of the WORSTED FACTORIES in GREAT BRITAIN and IRELAND; showing also the Number of Persons employed therein.

notice, and award Prize Medals to the following Exhibitors:—

**AKROYD, JAMES, and Son, Manufacturers, Halifax.** (190, Classes XII. and XV., p. 491.) The productions of this firm are eminently diversified and beautiful. The damasks are distinguished by elegance of design, richness of colour, and superiority of weaving. The "union damasks," composed of worsted and cotton, are noticeable also for economy of production. The satin Ture goods have a regularity, which shows that all possible care has been bestowed on their production. Some fabrics, entitled "Moirés d'Exposition," are remarkable for their novelty and the brilliancy of their effect. The articles made with silk warp and China grass are very beautiful. The patterns, colours, and combination of materials, are alike deserving of praise. The pouchos are well made and adapted for the markets of South America.

**BIÉTRY and Son, Manufacturers, 102, Rue Richelieu, Paris.** (356, France, p. 1194.) For cashmere fabrics of great fineness and regularity.

**BOTTOMLEV, MORRIS, and Son, Shelf, Bradford.** (165, Classes XII. and XV., p. 493-4.) The goods shown by this firm are woven with great regularity, and the designs of the figured fabrics are good.

**BOUCHEZ-POTIER.** (34, France, p. 1173.) For merinos of excellent manufacture.

**BROWN, W., Manufacturer, Halifax.** (129, Classes XII. and XV., p. 490.) For damasks composed of combinations of wool, silk, and cotton. Great taste is displayed in the designs; and in brilliancy of effect, and perfection of manufacture, the goods approach very nearly to those exhibited by Messrs. Akroyd.

**BRUHM and NÄGLER, Manufacturers, Gera.** (816, Prussia, p. 1095.) For cloths made with worsted weft and silk warp, well woven and dyed.

**CAILLET-FRANQUEVILLE, Marfeu.** (82, France, p. 1175.) For merinos of excellent manufacture.

**DAUPHINOT-PÉLARD, Manufacturer, Isles-sur-Snippes (Marue).** (471, France, p. 1200.) For merinos of excellent manufacture.

**DAVID, BROTHERS and Co., Paris.** (157, France.) For merinos, and cloths mixed with organzine and spun silk. The average of these fabrics is very good, the weaving satisfactory, and the colours and elegance of design very praiseworthy.

**DAVID-LAFRÉ and Co., Sains, Richaumont.** (138, France, p. 1178.) For the lowness of the prices at which their fabrics are produced.

**DELAETRE and Son, Manufacturers, Roubaix (Nord).** (142, France, p. 1178.) This firm is eminently distinguished by the excellence of its productions, and the specimens, now shown, fully justify the numerous distinctions which the French Government has, at several preceding Exhibitions, accorded to it. The Jury has noticed particularly a fabric, all wool, denominated "Chambard," of which the work is admirably perfect; the cloth named "Toile Victoria,"—equally beautiful; and the "satin de Chiné,"—made of the finest materials and with unequalled accuracy of workmanship. These goods occupy a very eminent position amongst the French productions, and in the judgment of the Jury fully entitle the manufacturers to a Prize Medal.

**DELFOSSE, BROTHERS, Manufacturers, Roubaix (Nord).** (144, France, p. 1178.) For great merit in the articles they display. The "Chambard" is very admirably manufactured, and some of the "satin de Chiné" are remarkably fine in their texture.

**FOSTER, JOHN, and Son, Manufacturers, Black Dyke Mills, near Bradford.** (143, Classes XII. and XV., p. 492.) The goods exhibited by this house are interesting, not only on account of their intrinsic excellence, but as displaying the great variety of fabrics produced in the worsted stuff trade. They comprise articles for ladies' dresses, coatings, vestings, linings and serges, umbrellas and parasol cloths, and damasks for hangings. The display of alpaca and mohair manufactures is remarkably varied, and the weaving is even and regular. The combination of materials is very good; several designs of the fabrics brocaded by the Jacquard looms are elegant, and

the effects well brought out. The coatings shown (of which large quantities are exported to the Continent and the United States of America) are distinguished by their stoutness, fineness, and general excellence.

**GOITCHKOFF, E. and J., Manufacturers, Moscow.** (189, Russia, p. 1373.) For cloths, "satin de Chiné," all wool, brocaded; fabrics of worsted and organzine silk warp, and cashmere-de-laines. These goods are distinguished by unsurpassed neatness of manufacture, excellence of design, and economy of production.

**GRÜNER, F. W., Glauchau.** (101, Saxony, p. 1109.) For merinos, all wool, of great regularity in weaving, and of excellent colours.

**HAAS, P. and Sons, Manufacturers, Vienna.** (259, Austria, p. 1019.) Damasks for furniture, of excellent combinations. The styles are magnificent, and the shades beautiful; and altogether the goods are of unquestionable merit.

**HOLDSWORTH, JOHN, and Co., Halifax.** (166, Classes XII. and XV., p. 494.) For damasks and other furniture cloths, which are well made, and of good colours and considerable variety; some of the styles being very elegant.

**HOOPER, G., CARROZ, and TABOURIER, Manufacturers, Paris.** (1625, France, p. 1255.) For a great variety of light goods of the Barège class, plain, checked, and brocaded, of excellent combinations. The cloth called "Bresilienné," though very difficult of execution, is admirably worked. Medal awarded in Class XIII.

**HORSEFALL, J. G., and Co., Manufacturers, Bradford.** (174, Classes XII. and XV., p. 491.) For fabrics made entirely of wool, and of wool combined with cotton and silk. The Jury have noted, as particularly deserving of commendation, the article denominated "Saxony cloth," for ladies' dresses. The weft is made from the finest Saxony wool, and the warp from the finest Australian wool, both combed by hand. The "Cobourgs," in cotton warp wefted with worsted, are admirable, and manifest a high degree of regularity, obtained by the excellence of the yarn employed and the talent of the weaver. The "Henrietta" cloths are made from spun silk warps and weft of the finest Saxony wool, and are distinguished by a softness, combined with firmness of texture, that has never been surpassed.

**HÖSEL, R. and Co., Chemnitz.** (86, Saxony, p. 1108.) For damasks of superior manufacture.

**JOWETT, THOMAS, and Co., Manufacturers, Bingley, near Bradford, Yorkshire.** (144, Classes XII. and XV., p. 492.) For a great variety of articles produced from alpaca weft, and silk and cotton warps, plain and figured. These goods are very well made, and show a good lustre. A new fabric of silk warp and linen weft is very neat, and affords encouragement for increased attempts in this direction.

**KAY, RICHARDSON, and WROE, Manufacturers, Manchester.** (186, Classes XII. and XV., p. 495.) For a very admirable range of Chiné goods produced from combinations of worsted, cotton, silk, and linen, with printed warps. These are distinguished by the excellence of the designs and the economy of their production.

**KUEFFER and STEINHAUSEN, Manufacturers, Greiz.** (528, Prussia, p. 1080.) For merinos and brocaded satins de Chiné.

**LOHSE, EDWARD, Manufacturer, Chemnitz.** (85, Saxony, p. 1108.) For damask goods, made with worsted and cotton, and worsted and silk. Their designs are in good taste, the combination of colours and materials very creditable, and the weaving of superior regularity.

**M'CREA, H. C. and Co., Manufacturers, Halifax.** (135, Classes XII. and XV., p. 491.) For damasks of great excellence.

**MATHIEU, ROBERT.** (France, 1443, p. 1245.) For merinos of superior manufacture.

**MILLEGAN, WALTER, and Son, Manufacturers, Bingley, Yorkshire.** (140, Classes XII. and XV., p. 492.) For a series of embroidered alpaca goods, produced by a process which they have patented; a style of manufacture noticeable for its elegance and novelty. The patterns are printed on white silk, and the greatest possible accuracy is necessary in the weaving, in order that the printing

blocks may fit; this point has been very successfully accomplished. All the designs are neatly executed, and the whole of the goods shown by this firm are highly creditable to their ingenuity and industrial skill.

**MOLLET-WARMÉ BROTHERS, Manufacturers, Amiens.** (648, France, p. 1109.) For goods composed of worsted, mixed with silk, largely used for foreign consumption. The designs are in excellent taste, and the fabrics of beautiful texture.

**MORAND and Co., Manufacturers, Gera.** (731, Prussia, p. 1090.) For draps d'été, or summer cloths, twilled like merinos, very creditable in their manufacture.

**MOURCEAU, —, Manufacturer, 27, Rue du Mail, Paris.** (1668, France, p. 1256.) For a remarkable exhibition of stuffs for furniture hangings, screens, table-covers, &c. The goods manifest an eminent superiority in their manufacture; being stout, woven with great care, and peculiarly rich in their effect. The colours are beautiful, and perfectly shaded; and the designs indicate an artistic taste. This species of manufacture is adapted, mainly, for the saloons of the rich and the elegant.

**PATURLE-LUPIN, SEYDOUX, SIEBLER, and Co., Manufacturers, Paris.** (1381, France, p. 1242.) This firm has long been celebrated for the decided superiority of its manufactures; and the fabrics now displayed fully maintain its high position. The merinos are of various qualities and admirable manufacture, the finer goods being especially beautiful; and, for evenness, softness, and fineness, never surpassed. The draps d'été, or summer cloths, are made with great skill. The "monseignes-de-laine," composed entirely of wool, the Bareges and Chalès, of wool and silk, and the bombazines, are also of great excellence. The yarns of which all these fabrics are made are most carefully spun from the choicest wool; the cloths are woven in the most perfect manner possible, and, altogether, the members of the Jury cordially unite in awarding a Prize Medal to this firm.

**PEASE, H. and Co., Manufacturers, Darlington.** (184, Classes XII. and XV., p. 495.) For Coubourg cloths, single and double twill worsted weft and cotton warp. The lower and middle qualities are much stouter than the majority of such goods, and are remarkably even and regular. The fine qualities are equally commendable.

**PESEL and MENURT, Paris.** (678, France, p. 1211.) For cashmere fabrics of great fineness and regularity.

**PETIT-CLEMENT, Manufacturer, Boulv. Marne.** (679, France, p. 1211.) For merinos of excellent manufacture.

**PIN-BAYARD, Manufacturer, Roubaix (Nord).** (682, France, p. 1211.) For fabrics all wool, of great excellence. The texture of the *satins de Chiné* is magnificent, and the yarn employed in them is perfectly spun.

**RAND, JOHN, and SONS, Manufacturers, Bradford.** (173, Classes XII. and XV., p. 494.) For a variety of articles made entirely of wool, and of wool combined with cotton and silk. The yarns employed are free from knots and irregularities, and the cloths produced are evidently woven with great care. The merinos made in the French style are without defects. The Coubourg cloths made from worsted weft and cotton warp are very excellent specimens of a fabric most extensively used for dresses; and the cloths made from worsted weft and silk warp are remarkably soft, fine, and even. The whole of these goods evidence the perfection which has been attained in this department of the worsted stuff manufacture.

**ROEGERS, GEORGE, Manufacturer, Bradford.** (142, Classes XII. and XV., p. 492.) For a series of Coubourg cloths, composed of worsted and cotton, of various qualities, which are praiseworthy for the regularity and evenness of their texture, and their economy of production.

**SALT, TITUS, Manufacturer, Bradford, Yorkshire.** (139, Classes XII. and XV., p. 491-92.) For a complete series of alpaca and mohair manufactures—(a branch of business carried on almost exclusively in England),—which illustrate, very strikingly, the great capabilities of these materials. The articles are of much variety, including fabrics composed of alpaca with cotton warps, and with silk warps yarn-dyed, and dyed in the piece: they are plain, twilled, figured, and *Chiné*, or made with printed warps. There are, also, goods composed of mohair with similar combinations. All are characterised by peculiar

lustre and brilliancy, equal in many cases to silk; they are also remarkable for regularity of texture, softness, and fineness. It may be confidently stated that similar goods have never before been produced; and the great increase in the consumption of articles of this description among all classes of the community, renders the display an interesting and important one. Mr. Salt was one of the first to introduce alpaca wool into the Bradford trade, and by his enterprise and skill has mainly contributed to the extent and perfection which this department of industry has attained. In addition to the articles already mentioned, Mr. Salt exhibits an assortment of moreens used for furniture hangings; one series being made from English wool, and the other from the Russian Donskoi fleece wool. Both are worthy of notice for the perfection of their manufacture; the latter, especially so, considering the difficulties in the way of successfully working up so coarse a material, which had never been effected prior to Mr. Salt having effected that object.

**SCHLUMBERGER, GASPARD, and Co., Manufacturers, Mulhouse (Haut-Rhin).** (1000, France, p. 1227.) For damasks for furniture hangings, composed of worsted and silk, woven with great regularity, and displaying superior taste in the designs of the patterns and the combinations of the colours. The effects produced are brilliant in the highest degree.

**SCHWANN, KELL, and Co., Proprietors, Bradford.** (141, Classes XII. and XV., p. 492.) The goods shown by this firm are different from those of any other Exhibitor, and confirm the observations already made on the variety of the fabrics produced by the Bradford manufacturers. They include Italian cloths, serges, says, and lastings, all worsted, and worsted combined with cotton, silk, and linen, of admirable manufacture; embossed alpaca lustres, "*Alepios de la Reyna*," velvets, &c. Some articles, called "*Shanghai dresses*," plain and watered, made from silk and China grass, are exceedingly beautiful. The whole of these goods are adapted for foreign markets. Messrs. Schwann, Kell, and Co., are merchants, and not manufacturers; but, as they have, at great expense and trouble, directed the preparation of the articles exhibited, as to texture, combination of materials, and dyeing, the Jury wish to mark their sense of the enterprise, taste, and public spirit shown by this firm.

**SUGDEN, JONAS, and BROTHERS, Manufacturers, Dockroyd, near Keighley, Bradford.** (167, Classes XII. and XV., p. 494.) For says, princettas, cubicas, shalloons, &c., made of English wool,—alone, and in combination with cotton. They are chiefly intended for foreign consumption, and they are of great regularity in the weaving, and highly creditable to the producers.

**TREMEL, A., and Co., Manufacturers, Bradford.** (147, Classes XII. and XV., p. 493.) For goods made chiefly for foreign consumption, consisting of worsted, alpaca, and mohair manufactures, shot with cotton, silk, and linen. The fabrics of these Exhibitors are commendable for their variety, good texture, and economy of production.

**VOGEL, WILLIAM, Manufacturer, Chemnitz.** (89, Saxony, p. 1108.) For damasks of great merit in their styles, colours, and combination of materials.

**VOLSER, —, Manufacturer, Moscow.** (190, Russia, p. 1372.) For *plain de laines* and "*Cashmere d'Ecosse*," made entirely of wool, which are distinguished by great regularity of manufacture. The "*satins de Chiné*," are nearly perfect in their make, and the colours are decidedly good. Bearing in recollection that Russia is only starting in this species of manufacture, the results now exhibited are quite wonderful.

**WEISSFLOG, E. F., Manufacturer, Gera.** (720, Prussia, p. 1090.) For merinos and broadened "*satins de Chiné*." Very superior fabrics, and the patterns elegant and tasteful.

**WINKLER and SON, Manufacturer, Rochlitz.** (91, Saxony, p. 1109.) For display of Chambard fabrics, merinos, &c., of good manufacture, and for their economy of production.

**ZIEGLER and HAUSMANN, Manufacturers, Glauchau.** (92, Saxony, p. 1109.) For merinos, all wool, remarkably

well made; "satins de Chiné," plain and brocaded; and figured goods, made of a combination of worsted and silk. All these are of good texture and commendable designs.

The Jury make Honourable Mention of the under-mentioned manufacturers:—

**BOTTOMLEY, WILKINSON, and Co.** (165, Classes XII. and XV., p. 493-4.) For satin-faced figured goods, made with worsted and cotton. These goods are exhibited by Mr. JACOB BEYRENS, merchant.

**BOUGHART, FLOIRIN, Tourecoing (Nord).** (1103, France, p. 1230.)

**CLOUGH, ROBERT, Keighley.** (151, Classes XII. and XV., p. 493.) For his merinos made from English long wool.

**CRAVEN, J. and SON, Prospect Mill, Thornton.** (149, Classes XII. and XV., p. 493.) For excellence of manufacture of Orleans cloth, composed of worsted and cotton.

**DALBY, JAMES, Bradford.** (152, Classes XII. and XV., p. 493.) For figured fabrics, composed of worsted and alpaca, with cotton and silk warps.

**DRUMMOND, JAMES, Bradford.** (150, Classes XII. and XV., p. 493.) For figured fabrics, composed of worsted and alpaca, with cotton and silk warps.

**ECROYD, WILLIAM, and SON, Lomeshaye, near Burnley.** (130A, Classes XII. and XV., p. 491.) For fabrics, including Colbours and mousselines-de-laines, made of worsted and cotton; bunting cloths for naval flags and signals, &c., made with great care. (Medal awarded in this Class for carded and Genappe yarns.)

**GREEN, R. F., and SONS, Manufacturers, Leeds.** (65, Classes XII. and XV., p. 488.) For Orleans cloths of excellent manufacture.

**GUILBERT and WATEAU, Manufacturers, Paris.** (860, France, p. 1221.) Their fabrics being of such a character as to merit commendation.

**HARRIS and FISON, Bradford.** (145, Classes XII. and XV., p. 492.) For a new and perfectly original fabric, made with web spun from the down or fur of the Angola rabbit. It is exceedingly soft, and much resembles cashmere. As an experiment to introduce a new material, it is very interesting and worthy of encouragement.

**HOADLEY and PRIDIE, Damask Manufacturers, Halifax.** (128, Classes XII. and XV., p. 490.)

**KERSHAW, S. and H., Laisterdyke, near Bradford.** (161, Classes XII. and XV., p. 493.) For excellence of manufacture of Orleans cloth, composed of worsted and cotton.

**MILNER, JOHN, and Co., Clayton, near Bradford.** (168, Classes XII. and XV., p. 494.) For excellence of manufacture of Orleans cloth, composed of worsted and cotton.

**SCHIEFFERS, F., Loth, Brabant.** (497, Belgium, p. 1166.) For a great variety of woollen stuffs, &c., which evince considerable merit.

**SHEPARD and PERFECT, Damask Manufacturers, Halifax.** (131, Classes XII. and XV., p. 491.)

**TAYLOR, J., and SONS, Damask Manufacturers, Halifax.** (88, Classes XII. and XV., p. 489.)

**WARD, J. W., Damask Manufacturer, Halifax.** (134, Classes XII. and XV., p. 491.)

**WILSON, J., Ovenden, near Halifax, Manufacturer.** (138, Classes XII. and XV., p. 491.) For ponchos of regular make, well adapted to the markets for which they are intended.

An article of a novel and unique character, contributed by Russia, deserves especial notice. It is made from camels' hair, spun by hand, and is produced by the Bashkirs, a wandering tribe on the banks of the Caspian Sea. The yarn is of astonishing regularity, and the texture remarkably good. The dresses made of it, the Jury are informed, are intended for Her Majesty the Queen of England.

HIS ROYAL HIGHNESS PRINCE ALBERT exhibits in Class XII. (p. 495) cashmere brocade fabrics, manufactured by Thomas Gregory and Brothers, of Shelf, near Halifax. These goods are composed of silk warp, and web of wool shorn from the Cashmere goats in Windsor Park, the property of His Royal Highness. The Jury have examined these goods with peculiar pleasure, as being the first

made from cashmere wool grown in this country, and as one amongst innumerable manifestations of the deep and active interest which His Royal Highness has ever taken in promoting and encouraging British manufactures. Viewing these goods as distinguishable for the novelty of the materials employed, and the opening thereby offered for the production of a new class of fabrics, the Jury have unfeigned pleasure in drawing attention to this contribution.

#### FLANNELS.

WALES is the country in which this article was originally made, and the flannel produced there is still held in high repute, and deservedly so, for vests worn next the skin, though it is not so cheap as some others. It continues to be chiefly manufactured by hand-labour, but few power-looms being employed. The finest is made from the fleeces of the flocks of the adjacent mountains. The supply exhibited is not large, but sufficient to show the peculiar quality and finish of this fabric.

LANCASHIRE, especially Rochdale and its neighbourhood, is the district where flannels are made more extensively than in any other part of the world, and in the greatest variety of widths, finish, and substance; that is, the thin gauze, the medium, and the thick, double-raised, or swan-kin quality; both for home consumption and exportation. Machinery is more generally used here than elsewhere; that is, the mule for spinning, and the power-loom for weaving. The greatest number of goods and Exhibitors are also from this district.

SADDLEWORTH and its neighbourhood are remarkable for the manufacture of Saxony flannels, especially those of very fine make, which have been very much admired in the London and other markets. A few are produced in the neighbourhood of Leeds, of common quality, and finished the natural colour of the wool.

In the west of England some white and dyed flannels and coatings are made, but not extensively. The fine dyed flannels partake somewhat of the quality of light cloths, but very few are in the Exhibition.

IRELAND supplies a few low flannels and coatings, commonly called Galways, made of Irish-grown wool, and adapted for the native population.

CANADA furnishes a few common and low flannels, but not much in this line has been yet attempted here. No prices were furnished for the few exhibited, nor do they profess to compete with those of England.

FRANCE.—There is considerable merit in the fine light flannels made in France. They are fine spun, and of a light texture, approaching nearest to the Saddleworth in wool and make: they are very suitable for printing, dyeing, and outer garments. The quantity exhibited is not large, but sufficient to show the style and quality: the prices are reasonable.

BELGIUM.—There is a very good assortment, especially from one house, here (but which furnishes no prices), of various kinds of flannels of the ordinary substance, and of medium and stout make, both twill and plain, white and dyed of various colours; and of domestics of cotton warps. The wool, make, finish, and dye are good.

UNITED STATES.—The few flannels exhibited from America are well made and finished. They are made from wool of the United States' own growth.

The Jury desire to record their high opinion of the flannels exhibited and manufactured by Messrs. KELSALL and HARTLEMORE, of Rochdale (466, Classes XII. and XV., p. 502), the excellence of which would have fully entitled them to a Prize Medal, had not Mr. HENRY KELSALL, one of the firm, been an Associate Juror; also the productions of Mr. ELIASHAW, of Ashton-under-Lyne, as exhibited by Mr. J. WILKES, 79 and 80 Watling-street, London. (6, Classes XII. and XV., p. 486.)

The Jury award Prize Medals to the following manufacturers, viz.:—

**BENOIST, MALOT, and WALBRAUNE, Rheims.** For fine flannels, well made and finished, and at reasonable prices. **CHATELAIN and FORON, Rheims, Marne.** (86, France, p. 1175.) For flannels of fine qualities, well made and finished, and at reasonable prices.

DR HEBELLE, *Ans.*, Manufacturer, Themester, Dowiers, near Verviers. (203, Belgium, p. 1157.) For a large assortment of white and dyed flannels, swanskins, mediums, and dometts, well made, dyed, and finished.

GILBERT and STEVENS, of Massachusetts. (441, United States, p. 1463.) For a good make of flannels of American grown wool, exhibited by JOHNSON, SEWELL, and Co., Boston, United States.

LEACH, J., and SONS, Manufacturers, Cailliards, Rochdale. (5, Classes XII. and XV., p. 486.) For a good general assortment of flannels, of meritorious make and finish, at reasonable prices.

LOYD, WILLIAM, and Co., Manufacturers, Newtown, Wales. (254, Classes XII. and XV., p. 498.) For the only assortment of real Welsh flannels, of good make and finish, and all made from the Welsh mountain wool.

SCHOFIELD, BROWN, DAVIS, and HALSE. 1 Gresham-street. (3, Classes XII. and XV., p. 486.) For a large assortment of meritorious flannels, well manufactured, and of new designs. The manufacturers of these are MESSRS. JOHN SCHOFIELD and Co., of Haybrook, Rochdale.

SMITH, J., and SONS, Saddleworth, near Manchester. (235, Classes XII. and XV., p. 497.) For merit in very fine well-made flannels.

TWEEDALE, J., and SONS, Manufacturers, Healey Hall, Rochdale. (4, Classes XII. and XV., p. 486.) For flannel of excellent make and finish.

#### MONEY AWARD.

The Jury award a prize of 10*l.* to J. BAMFORD, Manufacturer, Rochdale, Lancashire (237, Classes XII. and XV., p. 497), hand-loom weaver. For fine light gauze flannels, well spun and woven.

#### BLANKETS.

In Tuxis (pp. 5, 9, 11, 30) a very peculiar make of blankets is exhibited, some of these with a regular stripe across, others with alternate white and red stripes throughout, about an inch wide, made very similar to the gauze shawls worn by ladies in summer; also a very fanciful checked diamond pattern blanket, entirely knitted, the perfect workmanship of which possesses great merit.

The Jury award Prize Medals to the following Exhibitors:—

•ALBINET, jun., 19 Rue de la Vieille-Estrapade, Paris. (400, France, p. 1197.) For a small quantity of blankets, which are extremely fine.

EARLY, EDWARD. (269, Classes XII. and XV., p. 499.) For Witney blankets of a genuine character and moderate price.

EARLY, JOHN, and Co., Manufacturers, Witney, Oxfordshire. (268, Classes XII. and XV., p. 499.) For an excellent assortment of real Witney blankets, of sterling useful qualities.

FIRTH, E., and SONS, Manufacturers, Heckmondwike, near Leeds, Yorkshire. (37, Classes XII. and XV., p. 487.) For blankets with cotton warp, with good workmanship and cheapness combined. This is a new article of produce, and it has become a great branch of trade to the slave states of America.

GAMBLE, W., of Milton Mills, Dundas. (139, Canada, p. 966.) For fine specimens of blankets, and well made.

HAGUES, COOK, and WORMALD, Dewsbury, Yorkshire. (25, Classes XII. and XV., p. 487.) For a great variety of excellent blankets, in all qualities, for the Irish, English, and American markets; scarlet and blue blankets, for the American trade; and travelling rugs of various kinds.

PATTERSON, J., Dundas Mills. (146, Canada, p. 966.) For fine specimens of blankets, and well made.

ROBINSON, THOMAS, Dewsbury, Yorkshire. (54, Classes XII. and XV., p. 488.) For blankets. This person is a small manufacturer; but his goods are the best of their kind for quality and workmanship.

WILSON, J. J. and W., Manufacturers, Kendal. (245, Classes XII. and XV., p. 497.) For excellent qualities of railway wrappers and Windermere rugs, of good styles.

ZAALEBERG, J. C., and SON, Manufacturers, Leyden. (34, Netherlands, p. 1144.) These gentlemen have exhibited a fancy blanket, of particular merit.

The Jury desire to make Honourable Mention of the productions of the following gentlemen, viz.:—

BUFFAULT and TAUCHON, Issoune. (1122, France, p. 1232.)

GUYON, E., 57 Rue Galande, Paris. (1264, France, p. 1237.)

HOLDEN, B. T. and D., Concord, United States. (United States.)

THORNTON, FIRTH, RAMSDEN, and Co., Leeds. (32, Classes XII. and XV., p. 487.) Awarded in this Class.

ZUURDEEG, I., and SON, Leyden. (33, Netherlands, p. 1144.)

#### WORSTED AND WOOLLEN YARNS.

In reporting upon worsted, woollen, alpaca, and mohair yarns, we have agreed to class them under different heads, irrespective of the district or country whence they come,—and thus to speak of the merits of each spinner's yarn under the division of which it has formed a part. The Jury make no Report upon what are generally called Berlin or embroidery yarns, although in the English and foreign departments many samples were shown, which, so far as the character of the yarn (irrespective of colour) is concerned, were generally good; but as the merit of this article depends on shades of colour to as great, or even a greater, extent than on the character of the yarns, it was determined to leave the matter to be decided by other parties more competent to appreciate their peculiar excellence.

The Jury have divided the yarns which they considered to come within their province, into worsted, woollen, alpaca, mohair, cashmere, and mixture yarns, white and coloured. The worsted yarns again, although all come under the same general term, yet, being different in character, require to be mentioned separately. One class, which is the most numerous, the Jury will call "Merino Yarns;" another, "Lustre Yarns;" a third, "Genappe and Small Ware Yarns."

There might, perhaps, have been a further distinction made in the merino yarns; namely, between such as were combed by machinery and those which were combed by hand; but as this distinction was not in all cases expressed by the Exhibitors it has not been adopted. In woollen yarns, again, a further distinction might be observed; the term includes all such as are made from carded wool only, whether the same may have been from long or short stapled wool, fine or coarse. Wool, therefore, which has not passed through the process of combing, either by machinery or by hand, is termed "woollen yarn."

With these preliminary remarks the Jury begin their Report on worsted merino yarns. Of these there are a larger proportion than of any other, principally from France, the districts included in the Zollverein, and Austria. There were also one or two samples deserving of note shown by English spinners, and one sample by a Russian establishment. The samples of 160 twist shown by J. RAND and SONS, and of 144 shown by H. PRASE and Co., are very good indeed; but although deserving great credit, as specimens of throstle-spun yarn, yet the Jury were of opinion that the same yarn, had it been prepared on the French principle, spun on the mule, and equally well managed, would have been improved in character. The mule, which is in all but universal use on the Continent for spinning short-stapled wools, is (combined with the French mode of preparation) better than the throstle for the production of yarns adapted to the manufacture of merino cloths; and this circumstance, no doubt, has been the chief cause why the French have been able to take the lead through the world in merinos and mouseline-de-laine fabrics. The best specimens of yarn, both as to softness, evenness, and fulness of thread for the number, belonged to PATURLE-LUPIN and Co.; computed by the English number it was No. 178, or 200 millimetre, and we have never seen a more perfect specimen of worst yarn.

The French house which exhibited the nearest approach as to number was that of ROGER BROTHERS and Co.; but their yarn was not made from so fine a wool as that of Paturle-Lupin and Co., and certainly not so well managed

in the spinning; they were, however, upon the whole pretty good, especially their finest numbers of warp yarn.

The samples shown by the house of BILLIET and HUOT (p. 1251) were equal to the best in the spinning of the yarns, although not spun to so high numbers. The finest number of merino weft yarn exhibited by the LEIPZIG SPINNING COMPANY (185, English, p. 1106) was very good, and deserving of great praise, being very little inferior to that of Paturle-Lupin and Co. In addition to those already named, there were very good specimens of merino yarns shown by the following houses:—

HINDENLANG, sen. (p. 1238), LA CHAPELLE, and LEVARLET (p. 1238), LUCAS BROTHERS (p. 1240), PRADINE and Co. (p. 1243), CAUVET (p. 1232), FOURNIVAL, ALTMAYER, and Co. (p. 1187), HARTMANN and Co. (p. 1189), DELEGUE and Co. (p. 1178), A. THUM (p. 1017), L. THOMAS (p. 1017), VÖSLAU WORSTED YARN SPINNING COMPANY (p. 1017), A. SCHMIEGER (p. 1018), C. F. SOLBRIG (p. 1108), PETZOLDT and EHRET (p. 1107), WEISS, Jr. and Co. (p. 1090).

The Jury may also here mention a rather peculiar kind of Rarège yarn, said to be spun by the hand, exhibited by LANTEN and Co. (1205), used in the manufacture of very fine gauze cloth, chiefly for men's veils. In the medium numbers of merino yarns nothing appeared superior in management to a specimen of No. 72, shown by Mr. PRELLER, but spun by JONAS SMITH and SONS; this yarn was shown in connection with specimens of tops combed by the patent machine of Mr. Preller, and if these were an average of the work done by this machine, it has almost attained to perfection in clearing the wool from noil, as well as leaving the staple unbroken. The No. 72 named appeared to be made from an ordinary quality of Australian wool, yet the yarn was clearer, fuller, and more even than any other we examined of the same number. Perhaps it ought to be stated here, that as Mr. Preller, one of the Jurors, is a relative of the Exhibitor, he gave no opinion in this case, but left the other members to themselves in the examination of this specimen.

Although there were many more Exhibitors of merino yarns beside those named, whose yarns were upon the whole good, yet the Jury are of opinion that the houses already named excel the remainder in one or other either in warp or weft yarns.

In lustre worsted yarns very few samples were shown, as compared with the merino yarns; those exhibited by J. FOSTER and SON were thought the best. There was a good sample shown by WILLIAM THOMAS (p. 502), dyed in the preparation.

In woollen yarns, or such as were carded only (not combed), the specimens exhibited are numerous and generally good. Among the best of those which were carded from long-stapled wools, of low quality, were J. AKROYD and SON (p. 491), and FRANC and MARTELIN (p. 1236). In the fine numbers spun from better qualities of wool, there were beautiful yarns shown by CROUTELLE (NEPHEW) (p. 1177), SENTIS, SON, and Co. (p. 1227), LANTEN and Co. (p. 1205), XHOFFRAY and Co. (p. 1157), JOSEPH KELLER (p. 1217), CLARENBACH and SON (p. 1079), E. LEIDENFROST (p. 1017), and L. THOMAS (p. 1017).

There were also some good yarns shown by other houses, but not equal to those of the parties named.

The specimens of hosiery yarns shown by A. BURGESS and Co. (p. 497), BREWIN and WHETSTONE (p. 497), and WHITMORE and Co. (p. 497), were good, and gave full proof of the deserved fame which the Leicester houses have long maintained for the production of this class of yarns; there were also good samples of this kind shown by R. POPPLETON (p. 497), and J. G. SCHMIDT and SONS (p. 1106).

There were very few exhibitors of cashmere yarns; of these those exhibited by HINDENLANG, sen. (p. 1238), were the best. Their finest number was a beautiful specimen.

In yarns made from a mixture of silk and wool (mixed in the carding and preparation), there were samples shown both white and coloured, which, so far as we were competent to form a judgment, were very good; but as this branch of the worsted trade is comparatively new (at all

events to us), the Jury could not venture to give an opinion as to the relative merits of the different yarns of this class.

In alpaca and mohair yarns the samples shown appeared to be very good, both in evenness of thread and mixture of colours, for the various descriptions of fancy goods made from them. This branch of trade, although comparatively new, has made rapid strides towards perfection. A few years ago these raw materials were of little or no value, but through the skill and enterprise of those engaged in this trade, amongst whom Mr. T. Salt must by universal consent have a pre-eminent position, they have now become very valuable; and it cannot be doubted, from the beautiful specimens exhibited, that they are destined to maintain a high price as compared with ordinary qualities of sheep's wool. In the first stage of its progress, alpaca yarns were found to be very imperfect in their evenness for the manufacture of plain goods: this obstacle is now entirely overcome, and every specimen of alpaca yarn we examined was all but perfect in this respect.

Although the wool in its natural state is either black, brown, or white, yet from these three colours an almost endless variety is produced, enabling the manufacturer to secure shades adapted to all seasons. The specimens of fine numbers, exhibited by T. SALT (pp. 491-2) and J. FOSTER and SON (p. 492), show that it is capable of being spun so small in the thread as to render it available, either alone or in combination with cashmere yarns, or silk for fabrics of the lightest description.

Most of the samples of mohair yarn exhibited, single and folded, were very good, both in lustre and evenness of thread, especially those shown by T. SALT (pp. 491-2), J. FOSTER and SON (p. 492), STOWELL and SUGDEN (p. 502), and TOWNEND BROTHERS (p. 493). The mohair poplin yarn made by the last-named house, is the only yarn of this description prepared for the manufacture of poplin fabrics, and appeared perfect; they had also some beautiful specimens of coloured mohair yarns, suited for the small ware trade. There were also very good specimens of alpaca and mohair yarns exhibited by—

D. W. SHARP (p. 494), J. WHITLEY (p. 494), W. MILLIGAN and SON (p. 492), and BAUGHEN BROTHERS (p. 495).

The Genappe yarns shown were numerous and generally excellent in management: in the finer numbers of this class there are very good specimens shown by TOWNEND BROTHERS, and J. AKROYD and SON. The variety of small-ware yarns shown by J. SUGDEN and BROTHERS was very great, and their general management must give them a good position in the market for this class.

The Jury recommend as deserving of Prize Medals the exhibitors named below, who, to the best of their judgment excel in this class of yarns:—

AKROYD, J. and SON, Halifax. (130, Classes XII. and XV., p. 491.) For carded and Genappe yarns.

BILLIET and HUOT, 43 Rue du Sentier, Paris. (1550, France, p. 1251.) For merino yarns.

CLARENBACH and SON, Hütteswagen. (506, Prussia, p. 1079.) For woollen yarns.

CROUTELLE NEPHEW, Rheims (Marne). (132, France, p. 1177.) For woollen yarns.

ECROYD, W., and SON, near Burnley. (130A, Classes XII. and XV., p. 491.) For carded and Genappe yarns.

FOSTER, J., and SON, Manufacturers, Black Dyke Mills, near Bradford. (143, Classes XII. and XV., p. 492.) For alpaca, mohair, and lustre yarns.

HINDENLANG, sen., Crémouilly (Oise), and 24 Rue des Vinaigriers, Paris. (1269, France, p. 1238.) For cashmere and merino yarns.

KELLER, JOSEPH, Brünn, Moravia. (191, Austria, p. 1017.) For woollen yarns.

LACHAPELLE and LEVARLET, Rheims (Marne). (1285, France, p. 1238.) For woollen yarns.

LANTEN and Co., Rheims and Tinquieux (Marne). (566, France, p. 1205.) For Rarège and woollen yarns.

LEIPZIG SPINNING CO., Puffendorf. (44, Saxony, p. 1106.) For merino yarns.

- LUCAS BROTHERS, Bazancourt (Marne). (1331, France, p. 1240.) For merino yarns.
- PATURLE-LUPIN, SEYDOUX, SIEBER and Co., le Cateau. (1381, France, p. 1242.) For merino yarns.
- PEASE, H., and Co., Manufacturers, Darlington. (184, Classes XII. and XV., p. 495.) For merino yarns.
- RAND, J., and Sons, Bradford, Yorkshire. (173, Classes XII. and XV., p. 494.) For merino yarns.
- ROGER BROTHERS and Co., Trie Château (Oise). (1449, France, p. 1243.) For merino yarns.
- SALT, TITUS, Bradford, Yorkshire. (139, Classes XII. and XV., pp. 491-92.) For alpaca and mohair yarns.
- SCHMIDT, J. G., jun., Sons, Penig. (49, Saxony, p. 1107.) For folded card yarns.
- SCHMIDGER, A., Neudeck, Bohemia. (193, Austria, p. 1017.) For woollen yarns.
- SENTIS, SON, and Co., Rheims (Marne). (1011, France, p. 1227.) For woollen yarns.
- SOLRRIG, C. F., Chemnitz. (47, Saxony, p. 1107.) For merino yarns.
- STOWELL and SUGDEN, Bradford. (496, Classes XII. and XV., p. 502.) For mohair yarns.
- SUGDEN, J., and BROTHERS, Dockroyd Mills, near Keighley, Bradford. (167, Classes XII. and XV., p. 494.) For Genappe, mohair, and poplin yarns.
- TOWNEND BROTHERS, Cullingworth, near Bingley. (162, Classes XII. and XV., p. 493.) For Genappe and mohair yarns.
- XHOFFRAY and Co., Dolhain-Limbourg (Liege). (204, Belgium, p. 1157.) For woollen yarns.

The Jury also desire to make Honourable Mention of the two following houses:—

- CAUVET, Chantilly, near Paris. (1138, France, p. 1232.) For merino yarns.
- FOURNIVAL, ALTMAYER, and Co., Rethel (Ardennes). (221, France, p. 1187.) For merino yarns.

SAMUEL ADDINGTON, REPORTER.

*London, September 1851.*

## CLASS XIII.

## REPORT ON MANUFACTURES IN SILK AND VELVET.

[The figures after the Names (between Parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

*Jury.*

GEORGE TAWKE KEMP, *Chairman*, 35 Spital Square; Silk Manufacturer.  
 ARLES-DUFOUR, *Deputy Chairman*, France; Member of Central Jury.  
 THOMAS WINKWORTH, *Reporter*, Gresham Club, London; formerly Silk Manufacturer.  
 SAMUEL COURTAULD, 2 Carey Lane, Cheapside; Crape Manufacturer.  
 Lieut.-Colonel HENRY DANIELL, Turkey; Coldstream Guards.  
 THOMAS JEFFCOAT, Coventry; Ribbon Manufacturer.  
 HENRI MAHLER, Zurich.  
 ANTONIO RADICE, Austria; Vice-President of Chamber of Commerce, Verona.  
 J. VENTU, Sardinia.  
 CHARLES WARWICK, 132 Cheapside; Silk Warehouseman.

THE JURY of this Class have in their awards endeavoured to adhere to the instructions they received from the "Sub-Committee of Chairmen," as to the principles by which it was desirable they should be governed; and although in many cases the great merit of individual exhibitors seemed to justify such a deviation therefrom as would have enabled the Jury to recommend the Council Medal, they have abstained from so doing.

They have also made their awards rather with regard to individual merit, than to the rival claims which a comparison between the productions of exhibitors from different countries, or from the same country, might, if the Medals were limited in number, have rendered necessary. Had it been otherwise, the delicate, and to some extent invidious, duty of selection, where so much of approximation of merit exists, would have been still more onerous than they have felt it to be; and they confidently trust that credit will be given them for an anxious desire to do justice to all parties whose productions have been submitted to their inspection and judgment.

Not among the least of the difficulties under which the Jury have felt themselves placed, is that which arises out of the discretion they were allowed to exercise of naming exhibitors whose aggregate productions, though of high merit, are not yet sufficiently so to entitle them to Prize Medals.

It must be obvious that unless all these articles are of the first class as to quality, a line must be drawn between those which are and those which may be very nearly so: this the Jury have endeavoured to do, and in naming those exhibitors who in their judgment appear in this latter category, they think it better to abstain from mentioning the grounds on which in each instance their judgment is based.

As there is a very proper rule which prohibits Jurymen from receiving Medals in the Classes where they serve, the Jury can only mention that three of their number being exhibitors, no opinions on their productions are offered. They are Mr. J. VENTU, Silk Merchant, of Turin (p. 1303); Mr. Samuel Courtauld, of the firm of SAMUEL COURTAULD and Co, of Braintree, Bocking, and Halstead, also of London (p. 505); and Mr. G. T. Kemp, of the firm of STONE and KEMP, Silk Manufacturers, of Spitalfields (p. 504).

—The important position which the silk trade, in all its stages and branches, now occupies, would appear to call for an extended report on its present condition in each country where it is cultivated; but the Jury do not feel it to be any part of their duty to go beyond such notices as the several classes of productions to be found in the Exhibition, and comprised in Class XIII., may suggest. They do not possess the elements necessary to a statistical detail and historical *résumé* of this trade, and will therefore address themselves to such points of interest as may arise out of the awards they have made, taking the several countries which have exhibited in alphabetical order.

Before, however, they proceed to these particulars, it may be proper to remark, that with respect to the staple of this manufacture, the several samples to be found in the Exhibition afford but faint evidence of the great perfection to which the cultivation of the raw material has arrived in many countries. Although it has been assigned to the Jury of Section IV. to report on this department, it is so intimately connected with the thrown article, and forms so essential an ingredient in the production of perfect manufactured goods, that a passing observation may be excused. France alone has responded heartily to the invitation to exhibit cocoons, as well as reeled and thrown silks, no less a number than fifty-four producers having sent samples; while other countries in which it abounds, as Piedmont, Lombardy, the Roman States, the Tyrol, Spain, Turkey, India, and China, have together only supplied about fifty exhibitors. Naples, the immediate seat of a valuable quality of raw silk, has only contributed a single sample.

The importance of this material to France, as an article of national industry, may be gathered from the fact that the annual value of the quantity produced is stated to be not less than six millions sterling. What proportion this large amount bears to the aggregate or separate value of the products of the other countries just mentioned, the Jury have not the means of ascertaining: it cannot, however, but be very considerable.

## AUSTRIA.

The silk productions of this country, as seen in the Exhibition, consist principally of thrown silks, ribbons, garments, furniture, and ecclesiastical manufactured goods, handkerchiefs, crapes, &c., all of which are more or less indicative of a high state of cultivation, and reflect credit on the skill of the manufacturers.

## CHINA.

The exhibition of manufactured silks from this country, while it amply sustains the reputation she has long enjoyed for damask and other articles, is not sufficiently novel to justify more than a passing notice. The Jury have, however, much pleasure in tendering their thanks to Mr. H. H. LINDSAY (p. 1422), and to Mr. L. DENT (p. 604), for the beautiful collection they have made, and sent for inspection, of the goods peculiar to that nation.

## ENGLAND.

A very slight glance at the goods exhibited by the English manufacturers will enable those who have attended to the state of the silk trade of this country, to observe the great progress which has been made in quality, design, and cheapness during the last twenty years. Until within that period this branch of manufacture was comparatively inconsiderable, but it is now one of great importance, both as regards the quantity and value of the goods produced, and the extent of the markets opened

for their sale and consumption. It is remarkable that though the raw material is, like cotton, an exotic, the judicious application of skill and capital has overcome that natural impediment; and articles of extensive consumption, for the supply of which England was a few years since almost entirely dependent on foreign producers, are now nearly exclusively manufactured in Spitalfields, Lancashire, and other favourable districts. Of this fact the Exhibition furnishes many examples. The Jury do not allude to this as depreciatory of similar goods of foreign production, which are equally well made, but as illustrative of the beneficial effect of the policy by which the incubus of heavy duties on the raw and thrown material was removed, and that which operated as a practical prohibition on the foreign manufactured article was reduced to an almost nominal impost.

Goods are now made, both for the home and foreign markets, which were heretofore exclusively supplied by continental manufacturers. In Macclesfield, for instance, there are single houses which produce boys' ties, and ladies' silk handkerchiefs alone, both plain and fancy, to the extent of from 40,000 to 50,000 dozen per annum, averaging from 7s. to 20s. per dozen, employing 1500 hands, many of them under twenty years of age, and paying from 800*l.* to 1000*l.* per week in wages. In Essex, also, this liberal policy has been followed by results equally striking. Very extensive silk-throwing mills have been established in the towns of Colchester, Coggeshall, Braintree, Rocking, and Halstead; and in the three latter towns, where, under the system of heavy import duties or absolute prohibition, silk manufactures scarcely existed, articles of crape, gauze, and other similar fabrics are now produced upon the largest scale.

It may be doubtful whether excess of competition is not rather calculated to lower the standard of perfection than otherwise; but where, as in the silk manufacture, the market is the world, and the consumption unlimited, the scope for the exercise of taste and skill in all producing countries is proportionately extensive and profitable.

Before terminating these preliminary remarks, the Jury deem it right to mention that the house of LEWIS and ALLENNY, of London (p. 505), exhibit some brocaded silks of the highest order of artistic and manufacturing skill, of which they are the sole designers; but although they furnished both the pattern and the pecuniary means for producing it by the weaver, yet as they are not themselves manufacturers, the Jury did not conceive it to be within their province to award these exhibitors the Medal to which, under other circumstances, they would be entitled.

The Jury are of opinion that those only should have that distinction conferred upon them, in this Class, who embark their capital and talent in the manufacture of articles which, by the quantity and quality produced, assume a character of national importance; and that therefore an isolated case like the present, however meritorious, should not be made exceptional also. If the Jury had felt themselves justified in making exceptions to this rule, they would have noticed the silk goods exhibited by many firms, both wholesale and retail, which are distinguished by manufacturing talent and artistic taste. It is, however, due to their public spirit to make special mention of the following:—

CANDY and Co. (p. 1232); J. HOWELL and Co. (p. 505); MARSHALL and SNEEGROVE (p. 505); J. W. PUGH (p. 503); REDMAYNE and Co. (p. 503); SEWELL, EVANS, and Co. (p. 504); SWAN and EDGAR (p. 504); and TUVÉE and Co., of Paris (p. 1212).

#### FRANCE,

Long the cradle and chief seat of the silk manufacture, amply sustains its position in the present Exhibition. It would be difficult to do adequate justice to the varied claims of the throwster, dyer, designer, and weaver, of the magnificent assortment of goods which occupies the department assigned to that country, and which excites the admiration of all who take an interest in this important branch of industry. The Jury have had no hesitation in awarding Medals to the large number of exhibitors

whose names will be found below, and have reluctantly omitted others whose merits are scarcely less deserving of that mark of distinction. The well-merited reputation of the manufacturers of France, and the number and extent of the European and transatlantic markets they have hitherto so largely supplied, supersede the necessity for extended observations. The Jury cannot, however, conclude this brief notice without directing attention to the striking fact, that although Lyons has been unfortunately too frequently exposed to fierce local disturbances, and has shared in the misfortunes, which attend national revolutions, the peculiar trade of the district has not degenerated in character or importance—a fact which they attribute mainly to the circumstance that prohibitive duties, which oppress other branches of manufacture, are removed from this.

#### GREECE

Only exhibits a few articles of comparatively small importance.

#### HOLLAND.

The same remark applies to the comparatively small assortment from this country.

#### INDIA.

The manufactured silks from this important dependency of the British Empire which have been exhibited, are inconsiderable in quantity, and not very novel in character. The Jury have been unable to award Medals to exhibitors, not only for this reason, but also because the parties exhibiting are not the producers or manufacturers. They are not, however, the less entitled to thanks for their liberality in causing the samples found in this department of the Exhibition to be manufactured and exhibited.

#### ITALY.

The reputation of this country, as the chief producer of the raw and thrown material, is well sustained by the samples exhibited. Manufactured goods of great merit are also to be found in this department, among which the velvets of Genoa and Turin must be signalled as fully sustaining their ancient character for beauty and quality.

#### PORTUGAL.

The manufacturers of this country exhibit a small assortment of rich gold and silver brocades for ecclesiastical purposes, and miscellaneous articles in gauze, velvet, satin, &c., but nothing of sufficient importance to merit special notice. Considering the advantages of climate, and the abundant labouring resources which this country enjoys, this sterility of skill, enterprise, and application is much to be regretted.

#### RUSSIA.

Although, as before observed, raw silks are not comprised in their Class, the Jury have noticed some very fair samples from this country; which, as also some thrown silks, afford promise of an important branch of trade being opened at no distant period. The same may be emphatically said of the manufactured silks to be found in this department. They are highly creditable to the producers, whether as regards the choice of the material, the colours, the design, or the manufacture. Some magnificent silks for furniture and ecclesiastical purposes deserve special notice.

The progress made in this important branch of manufacture during the last few years, is illustrative of the advantages which seldom fail to result from the removal of prohibitory duties, and the introduction of a low tariff.

#### SPAIN.

The Jury have only been able to award one Medal to an exhibitor from this country; but specimens of good raw silk, and of considerable manufacturing merit in ribbons, broad silks, &c., may be found in this department.

A very little attention to details might make this branch of manufacture of great importance to the country.

## SWEDEN AND NORWAY.

The few articles exhibited by these countries offer no feature for particular notice.

## SWITZERLAND.

The character of the silk manufacture in this country demands a discriminating notice. The goods exhibited are of a low class, as to weight and texture, but are well made in all respects. The material employed is generally from Italy, and excellent of its kind; the workpeople are economical in their habits; the manufacturers confine their attention to the precise kinds of goods which best suit their localities, and their means of obtaining a regular sale for them; and, altogether, a trade of much importance is sustained with Germany, Russia, Italy, and the two Americas.

Forty-two manufacturers of the canton of Basle exhibit. In one case (152) are shown the united contributions of twenty-six ribbon manufacturers. This case contains some very good specimens of figured ribbons, which are clearly indicative of the improved condition of this trade in that district.

## TURKEY.

The silk fabrics sent from this eastern part of the globe exhibit a peculiarity of taste and execution, such as might have been expected from a country so essentially different in all its habits from those of Europe generally. While there is much to excite curiosity, and even admiration, there are no goods so strikingly superior and novel as to justify the Jury in awarding more than two Medals. There is, however, in the articles exhibited by this country, the most satisfactory evidence that at length the more intimate intercourse with other countries which steam navigation has superinduced, has begun to tell favourably on their national character and domestic economy. It appears that, with the introduction pretty generally by the Sublime Porte of European attire, a relish for business, and an aptitude for mercantile transactions, have supervened. To the active exertions of the Turkish Consul-General, M. ZOTIRAN, we are mainly indebted for the highly creditable display of goods in this department of the Exhibition, in which are to be found cocoons, raw and thrown silks from Brussa, Salonica, Adrianople, and Syria; manufactured silks from Constantinople, many of them very rich and handsome; and similar goods, made under the immediate superintendence and with the pecuniary assistance of the Turkish Government. The Jury would also direct attention to the light silk shirts, made from a comparatively inexpensive and otherwise useless raw material, specimens of which are worn by the boatmen who take charge of the graceful caique now floating on the Serpentine, and sent as a model of the boats which line the shores of the Bosphorus. There are other woven fabrics, particularly some gold embroidery peculiar to Constantinople and Smyrna, which deserve notice, but which do not belong to this class.

## ZOLLVEREIN.

In this department, embracing the manufacturing talent of a large portion of Germany, including Prussia, a considerable variety of silk goods is exhibited. The greater part, however, are of low qualities, suitable only to the home and the American markets, in both which they command an extensive sale. The velvets are perhaps the most important of these products, and are characterised by the regularity and evenness of the pile, and the economical application of the skill and labour necessary to their manufacture. They are articles which are largely exported from Crefeld and Vierzen, which are the chief seats of this peculiar branch of the silk trade.

The Jury award Prize Medals to the following Exhibitors:—

## THROWN, SEWING, AND SPUN SILK.

ALBON, ROBIN, and Co., of Leek (48, p. 506), for some excellent samples of sewing silks.

FARRIS BROTHERS, St. Julien en St. Alban (Ardèche),

(41, France, p. 1173), for the perfection of their trams for tulle, and for orgazine 16/18, 20/22, and 26/24 deniers, for satin and plush.

BONNETON, J., St. Vallier (Drôme), (771, France p. 1217), for his orgazine for plush and satin.

BRAVO, MICHAËL, Pignerol (24, Sardinia, p. 1303), for excellent orgazine for satins.

BRIDGETT, THOMAS, and Co., of Derby (49, p. 506), for sewing silks, purse twist, and sarsnet ribbons.

BROUGH, J. and J. and Co., of Leek (44, p. 506), for some excellent samples of sewing silks.

CHAMBON, CASIMIR, Alaix (Gard), (113, France, p. 1170), for his fine six-thread grenadine, for the manufacture of "tulle bobin," and for his orgazine 26/28 deniers, for satin.

CHARTRON and SON, Vallier, Drôme (796, France, p. 1218), for orgazine 13/13 deniers, for tulle; 32/34, for ribbons; and 19/20, 24/26, and 26/28, for plush and satin.

COUDERC and SOUCARET, Montauban (Tarn and Garonne), (96, France, p. 1176), for gaze à bluter (used by millers), of extraordinary perfection, numbering from 10 to 220 threads per inch.

DUMAINE, XAVIER, Tournon (175, France, p. 1181), for orgazines 18/19, 20/21, and 26/28 deniers.

HADWEN and SONS, of Halifax (42, p. 505), for beautiful spun silk yarns in all numbers.

HERME, AUGUSTE, Crest (537, France, p. 1204), for orgazine 18/19, 26/28, and 32 deniers, for satin.

HOLDFORTH and SON, of Leeds and Coughton (61, p. 506), for spun silk yarns in all numbers, in the production of which they appear to have arrived at a high point of perfection.

JAME, BIANCHI, and DESIGNEUR, Lyons (Rhône), (1087, France, p. 1230), for grenadine and orgazines. The Jury consider the productions in raw silk of M. Duseigneur, and of other exhibitors of this material, as belonging to Class IV.

LANGEVIN and Co., Laferté Aleps (Seine-et-Oise), (898, France, p. 1223), for spun silks, in great perfection, from the lowest to the highest numbers.

MENET, JEAN; Beauchien and Annonay (Ardèche), (1657, France, p. 1256), for beautiful qualities of orgazine, both white and yellow, especially those which are suitable for the difficult and delicate manufacture of blondes.

POUDEBARD, N., di Portici, near Florence (51, Tuscany, p. 1291), for orgazines and trams 22/24 and 36/40 deniers.

RIGNON, F. and Co., of Piedmont (30, Sardinia, p. 1309), for excellent orgazine for satins.

SCHETTLER and Co., of Milan (80, Austria, p. 1011), for orgazine, 28 deniers for satin, and for their grenadine, 48 deniers in four threads.

SOUREYRAND, LOUIS, St. Jean-du-Gard (1490, France, p. 1248), for orgazine 18/20 and 26/28 deniers.

TEISSIER DU CROS, L. and E., Vallerangue (1031, France, p. 1228), for orgazine from 20/21 to 32 34 deniers, and for grenadines. (Prize Medal, Class IV.)

VERZA BROTHERS, Milan (87A, Austria, p. 1012), for trams.

## RIBBONS.

BALAY, JULES, of St. Etienne (1064, France, p. 1229), for ribbons made of silk in the gum, and dyed afterwards. They are well finished, and command a considerable sale.

BUISSON and Co., of St. Etienne (1125, France, p. 1232), for the good taste and quality of their gauze ribbons.

COLLIARD and COMTE, of St. Etienne, Loire (1154, France, p. 1233), for the assortment of ribbons, which are considerable in quantity, novel in design, and creditable to the manufacturer and draftsman in every way.

COPE, HAMMERTON, and Co., of Coventry (70, p. 507), for an assortment of figured ribbons made by power, which is good, when taken in connection with price.

CORNEIL, LVELL, and WEBSTER (22, p. 504), of London and Nuneaton, for ribbons which are in good taste, well executed, and the colours judiciously blended.

COVENTRY RIBBONS COMMITTEE (72, p. 507), for a ribbon exhibiting much taste and skill in its production.

COX, R. S., and Co., of London and Coventry (66, p. 507), for an assortment of fancy ribbons of good qualities and mixtures.

DE BARY and BRISCHOFF, Basle (152, Switzerland, p. 1275), for good specimens of figured ribbons.

FREYVOGEL and HEUSLER, Basle (162, Switzerland, p. 1275), for good specimens of figured ribbons.

LANCHER, FAURE, and Co., St. Etienne, Loire (1293, France, p. 1238), for good specimens of ribbons.

MESSEAT, ANTON, Vienna (246, Austria, p. 1019), for an assortment of figured taffetas, gauze and crape ribbons, well manufactured.

MORRING, CHARLES, Vienna (247, Austria, p. 1019), for a good and well executed assortment of figured and chiné ribbons.

RICHTER, LINDER, Bâle (152, Switzerland, p. 1275). The ribbons exhibited by this manufacturer are all plain satin, of different qualities, and woven in the gum. Some are left undyed, to show the process. They command a large sale on account of their comparative cheapness.

SARASIN and Co., Basle (152, Switzerland, p. 1275), for good specimens of figured ribbons.

SARASIN, J. F., Basle (152, Switzerland, p. 1275), for good specimens of figured ribbons.

SOLLER and Co., Basle (152, Switzerland, p. 1275), for good specimens of figured ribbons.

SULGER and STÜCKELBERGER, Basle (152, Switzerland, p. 1275), for good specimens of figured ribbons.

VIGNAT BROTHERS, St. Etienne (1524, France, p. 1249), for chiné ribbons, which are beautifully designed and executed; and for some specimens of figured ribbons.

#### MANUFACTURED SILKS.

ANDREAE, C., of Mulheim on the Rhine, near Cologne (360, Prussia, p. 1071), for plain velvets and stamped fancy velvet ribbons, in good taste and cheap.

BALEIDIER, F., of Lyons (1065, France, p. 1229), for an excellent assortment of vestings in large variety, both plain and fancy; and for the figured velvets and terry, which also bear testimony to his extensive knowledge of the resources of the Jacquard loom.

BARTH, MASSING, and PLICHON, of Sarreguemines, Moselle (21, France, p. 1172), for an assortment of black silk plush for hats, remarkable for the brilliancy of the colour and the excellence of the workmanship.

BAUMAN and STREULI, of Horgen (153, Switzerland, p. 1276), for plain and armure silks of the best workmanship, and for shot or glacé gros-de-Naples, which are excellent for a low-priced article.

BELLON, JOSEPH, and Co., of 2 Rue du Griffon, Lyons (1079, France, p. 1229), for black satins and taffetas, in great perfection as to colours and qualities, and variety as to price.

BERNOVILLE, LARSONNIER, and CHENEST (1548, France, p. 1250), for printed silks, plain coloured grenadines, and novelties in silk-gauze dresses, all in excellent taste. Medal awarded in Class XVIII.

BERTRAND, GAYET, and DUMONTAT, of Lyons (1085, France, p. 1230), for a beautiful assortment of chiné and figured silk shawls, scarfs, and cravats, in excellent taste.

BRISCHOFF, CHRISTOPHER and JOHN, of Basle, (152, Switzerland, p. 1277), for black taffetas, and gros-de-Rhin, of excellent quality, and remarkable for the brilliancy of the colour; also for some good black satins.

BONNET, J. and Co., of Lyons (197, France, p. 1230), for black satins, from 2f. 75c. to 14f.; and black taffetas, from 4f. 25c. to 8f. 25c. These manufacturers confine their operations to these two articles, and have attained to great perfection in the production of them.

BOUVARD and LANCON, of Lyons (1110, France, p. 1231). This house enjoys a high reputation for silks suitable for furniture and ecclesiastical purposes, and had prepared a large assortment for exhibition on this occasion, which was unfortunately consumed by a fire on the 31st of March last, which destroyed their premises. For the few specimens of their looms now shown, which exhibit manufacturing talent of a high order, a Prize Medal is awarded.

BRISSON BROTHERS, Lyons (1117, France, p. 1232), for

black silk plush, of excellent quality, principally made by power.

BROCKLEHURST, J. and T., and SONS, Macclesfield, (38, p. 505), for Persians, serges, sarsonets, gros-de-Naples, handkerchiefs, &c., in great variety, and well made.

BROSSE and Co., Lyons (1118, France, p. 1232), for coloured velvets in great variety, and well manufactured.

BRUNET, LECOMTE, GUICHARD, and Co., of Lyons (1120, France, p. 1232), for a most splendid assortment of chiné and embroidered silk gauzes, grenadines, and crêpes for dresses, shawls, collars, scarfs, and cravats, the execution of all which is admirable in taste and in mixture of colour. Their printers, Perrigaux, Brunet, and Co., deserve great praise for the skill displayed by them in that department of art.

CAMPBELL, HARRISON, and LLOYD, of London (31), for some beautiful specimens of moiré antique; figured and brocaded silks, which are very superior in quality, taste, and execution.

CARQUILLAT (Weaver), of Lyons (1134, France, p. 1232), for a woven portrait of Pope Pius IX., and another woven picture of the visit of the Duc d'Angoulême to his workshop; and in the compartment occupied by Messrs. Pottin and Lamhand there is also a portrait of the Queen by this superior weaver, all of which are executed with artistic skill of a high order.

CARTER, VAVASSEUR, and RIX, of London (30, p. 505), for figured silks and moiré antique.

CASEY and PHILLIPS, of Spitalfields (23, p. 504), for plain black Radzimore and other plain silks, all of which are well made.

CHAMBER OF COMMERCE OF LYONS, for a magnificent assortment of fancy silks, in great variety, of the richest quality, in exquisite taste, of the choicest colours, and the best manufacture (awarded an unclassified Council Medal.)

CHAMPAGNE and ROUGIER, of Lyons (1143, France, p. 1232), for a magnificent assortment of rich figured silks, in great variety of design and mixture, including some exquisite specimens of rich broché, at 36f. per mètre.

CHICHIZOLA, J., and Co., of Turin and Genoa (39, Sardinia, p. 1304), for an assortment of plain velvets, peculiarly fresh and brilliant in colour, and admirably manufactured; also for figured silks, well made, in good taste, and in considerable variety.

CRITCHLEY, BRINSLEY, and Co., of Macclesfield, (40, p. 505), for a great variety of figured silks, handkerchiefs, and cravats, in good taste, well made, and cheap at the prices quoted.

DIERGARDT, F., of Viersen (509, Prussia, p. 1079-80), for plain velvets, figured velvets for vestings, and an assortment of velvet ribbons in all qualities, all of which are excellent of their kind.

DONAT and Co., Lyons (1193, France, p. 1234), for black silk plush, of excellent quality, principally made by power.

DONAT, ANDRÉ, of Lyons (1192, France, p. 1234), for an immense variety of vestings and silks for cravats, in plain, figured and broché satin and grenadine. Also for some of the former in velvet grounds, brocaded in gold and silver; and for plain and figured moiré antique, the whole displaying fine taste, and artistic skill of a high order of merit.

FONTAINE, FR., of Lyons (1225, France, p. 1236), for a similar exhibition of vestings and garment silks of equal merit.

GABAIN, GEORGE, of Berlin (119, Prussia, p. 1055), for a good assortment of silks in damask and brocatelle for furniture, in good patterns, and well executed.

GINDRE, L., and Co., of Lyons (1247, France, p. 1237), for white and coloured satins, from 3fr. to 7fr., which are well made at the prices quoted.

GIRARD, NEPHEW, and Co., of Lyons (1248, France, p. 1237), for black and coloured velvets, in great variety, and admirably manufactured.

GRAHAM and SONS, of Spitalfields (17, p. 504), for black moirés, satins, and velvets, well manufactured.

GROSVENOR, W. and Co., of Kidderminster (52, p. 506), for furniture silks in great variety, of good design and texture, especially at the prices quoted.

GAOUT and Co., of London (36, p. 505), for black crapes, crêpe acrophane, crêpe lisse, &c., all well manufactured and in good colours.

GUILLLOT and Co., of Turin and Genoa (41, Sardinia, p. 1304), for plain velvets of great excellence; for figured velvets for tapestry and furniture, remarkable for their width, good taste, and the ingenious method of weaving; and also for a beautiful imitation of white lace on velvet ground, in several varieties.

HARBOP, TAYLOR, and PEARSON, of Manchester (62, p. 506), for a good assortment of black and shot plain silks, well made at the prices quoted.

HECKEL and Co., of Lyons (870, France, p. 1221), for satins in white, black, and colours, of all qualities, which are probably the finest specimens of which the article is susceptible.

HELL, GEORGE, of Vienna (260, Austria, p. 1019), for a considerable assortment of brocatelles, in excellent taste, and well made. Some of these show the design on both sides, and others are to be noted for their unusual width.

HILL, JAMES, and Co., of Spitalfields (25, p. 505), for plain and figured silks, well made, and cheap at the prices quoted.

HOEHN and BAUMANN, of Horgen (53, Switzerland, p. 1276), for lustrings, which are well made for low-priced goods.

HOOPER, G., CARROZ, and TABOURIER, Paris (1625, France, p. 1255), for plain, figured, and printed silk gauzes, well made and printed. Also for an assortment of illusion tulle, peculiar to the house, of excellent colours; and for a great variety of other goods deserving special notice.

HOULDSWORTH, JAMES, and Co., of Manchester (64, p. 506-07), for furniture silks in great variety, of good design and texture, especially at the prices quoted.

IBRAHIM AGA, Turkey (p. 1390), for specimens of figured velvets, of some taste and well made.

KEITH and Co., of London, Manufacturers (1, p. 504), for a great variety of furniture silks, in excellent taste, and exceedingly well made.

KOLOKOLNIKOFF, PAUL, of Moscow (203, Russia, p. 1373), for magnificent specimens of gold and silver brocade, chenille, and other textures, principally for ecclesiastical purposes, from about 60s. to 70s. per yard.

KONDRASSHEFF, of Moscow (353, Russia, p. 1383), for a variety of silks in brocade, damask portraits à la Jacquard, and other textures, in great variety of design and of good taste.

LAFAYE and DOLBEAU, of Lyons (1292, France, p. 1238), for a beautiful assortment of damask reps, and some figured and chiné silk shawls.

LEXMANN, J., and SON, of Vienna (265, Austria, p. 1019), for brocatelle, embroidered in gold and silver, for ecclesiastical purposes. Also for broché gold on chenille and velvet grounds. The assortment is generally superior, and well deserving of notice and commendation.

LE MARE and SONS, of Spitalfields (21, p. 505), for black and coloured velvets, satins, moiré and glacé silks, some of which are made by power, and are cheap at the prices quoted.

LE MIRE and SON, of Lyons (1649, France, p. 1256), an old-established and eminent firm, for some beautiful specimens of their earlier productions of figured silks for furniture of churches, combined with their newest styles in lampas, damask, brocatelle, and embroidery in gold and silver, for ecclesiastical vestments, and other purposes requiring even the introduction of jewellery.

MARTIN and CASIMIR, of Lyons (612, France, p. 1207), for an excellent assortment of black silk plush, from the highest to the lowest qualities, principally made by power. They produce annually in this article to the value of about 180,000*l*.

MASSING, BROTHERS, HUBERT, and Co., of Paris (333, France, p. 1303), for a similar assortment made by power.

MATHEVON and BOUVARD, of Lyons (1349, France, p. 1240), for some splendid specimens of rich silks for churches and ecclesiastical vestments, as well as for furniture in lampas, damask, brocatelles, and reps, worked in bouquets of flowers, in gold, silver, and silk, the cost of some being 300*l*. per mètre, and the mere labour of

which costs from 60*l*. to 70*l*. per mètre; for moiré antique shot gold and silver, of the highest perfection; and for the woven medallion of Her Majesty, in a garland of natural flowers, beautifully designed and executed.

MEMORIUS BROTHERS, of Viersen (530, Prussia, p. 1080), for a large variety of plain and fancy velvets, and velvet ribbons, well made, and cheap at the prices quoted.

MOLINARI, A., of Genoa (43, Sardinia, p. 1304), for plain velvets, and also for rich figured velvet for furniture, in antique designs and styles.

MONTESSUY and CHOMER, of Lyons (1360, France, p. 1241), for crêpes, crêpe lisse, crêpe acrophane, and gauze of many kinds, all of which are very well made, and cheap at the prices quoted. They are manufactured by power.

MUSTAPHA, AGA HADOL, Turkey (596 and 663A, p. 1392), for crapes.

NAEF and SCHWARZENBACH, of Thorweil (153, Switzerland, p. 1276), for lustrings and gros-de-Rhin, of various qualities, which are well made, and cheap at the prices quoted.

ORDUNA, V., Valencia (214, Spain, p. 1342), for damasks, velvets, and other silks of great merit.

POLLAKOFF and ZAMBIATI, of Moscow (205, Russia, p. 1373), for magnificent specimens of gold and silver brocade, of great originality and splendour, from 60s to 80s. per yard.

PONSON, C., of Lyons (1403, France, p. 1243), for plain silks, of different kinds and in great variety, particularly in place, all of which afford satisfactory evidence of the great skill and attention of the manufacturer.

POTTON, RAMBAUD, and Co., of Lyons (1402, France, p. 1243), for a beautiful assortment of rich figured silks, in excellent taste. Their execution of a woven picture, from the original by Winterhalter, of Her Majesty, Prince Albert, and the Prince of Wales, merits the highest commendation as a work of art.

REYNIER, Cousins, of Lyons (1435, France, p. 1245), for a great variety of very superior velvet, gauze, satin, and taffeta handkerchiefs, collars, shawls, and scarfs, in excellent taste.

REICHARDT, F., of Vienna (268, Austria, p. 1020), for plain, figured and moiré silks, and for black and coloured satins, all of which are well made and in good taste. A piece of wide black satin deserves particular notice for its quality and finish.

RELIQUET and SILVENT, of Lyons (1432, France, p. 1244), for a beautiful assortment of fancy vests in velvet and plush, in great variety and of excellent taste. This firm also exhibits a choice assortment of stamped velvet ribbons, of great merit.

ROBINSON, J. and R. and Co., of London (5, p. 504), for velvet vestings, black armozines, silks and satins for cravats, &c., all in good designs, and well made.

ROBINSON, J. and W. and Co., of London (24, p. 504), for a great variety of satins, serges, velvets, plush, &c., for drapers and tailors, all of which are well made.

ROBINSON, J. and T., of Spitalfields (6, p. 504), for black and coloured velvets.

RYFFEL and Co., of Staefta, Switzerland (153, Switzerland, p. 1276), for half-Florence, Florence, and marcelline, which are all good at the prices quoted.

SANDERSON and KLEID, of London (3, p. 503-4), for figured vestings, in good designs and well made.

SAPOGNIKOFF, ILLINS OF, of Moscow (372, Russia, p. 1384), for magnificent specimens of gold and silver brocade and other textures, chiefly for ecclesiastical purposes, excellent in design and good in execution.

SCHIEDLER and Co., of Crefeld (534, Prussia, p. 1080-81), for a large variety of plain and fancy velvets and velvet ribbons, well made and cheap at the prices quoted.

SCHOOL OF DESIGN, in Spitalfields (37, p. 505), for a brocaded silk, of considerable merit as to taste and execution.

SCHOPFER, M. A., of Vienna (270, Austria, p. 1020), for an assortment of brocatelles, good in taste and quality.

SCHWARZENBACH, F. J., of Kilchberg (153, Switzerland, p. 1276), for gros-de-Rhin and poul-de-soie, all in good colours, well made, and cheap.

SEAMER, THOMAS, of London (15, p. 504), for moiré antique and plain velvets, well made.

SIMONS, J., HERS or, of Elberfeld (514, Prussia, p. 1080), for a great variety of velvets, figured silks, cravats, handkerchiefs, scarfs, vestings, gauzes, &c., all indicating skill, taste, and good knowledge of all the appliances of their manufacture.

SOLEY, B., Turin (40, Sardinia, p. 1304), for rich figured silks, armures and a royale ground, for furniture; and for some gauze diaphane for the same purpose; all which are in good design, texture, and quality.

STAFFER, J., of Horgen (153, Switzerland, p. 1276), for plain, coloured, striped, and checked gros-de-Naples, which are neat in style and well made.

STAUD BROTHERS, of Horgen (153, Switzerland, p. 1276), for figured silks deserving especial notice, exhibited by the canton. They are in good taste, and well made for the qualities and prices at which they are produced. The arms of the canton, woven in silk, deserve attention.

TEILLARD, C. E., of Lyons (1030, France, p. 1225), for plain glacé silks, armures in great variety, moiré antiques of the best colours, qualities, and execution, and rep silks; all of which are excellent in every respect.

VATIN and Co., of Paris (1704, France, p. 1258), for an excellent assortment of fancy silk gauzes, dresses, and shawls, some brocaded and very rich.

VOM BRUCK, H. SONS, of Crefeld (535, Prussia, p. 1081), for an assortment of plain velvets and velvet-ribbons, which are cheap at the prices quoted.

WALTERS and SONS, of Spitalfields (9, p. 504), for black plush for hats, in various qualities.

WARDLE, H. and T., Macclesfield (41, p. 505), for figured silks, handkerchiefs, and cravats.

WINKWORTH and PROCTER, of Manchester (65, p. 507), for shot and glacé gros, of excellent texture; also for figured and chiné silks, in chaste designs and mixtures of colour, all of which are characteristic of the taste and skill of the manufacturers.

ZELLER, FELIX, and SONS, of Hirslanden (153, Switzerland, p. 1276), for gros-de-Naples and satinet, both jaspé; all of which are in good taste and well manufactured.

ZURREN, JACOB, of Hausen (153, Switzerland, p. 1276), for Persian and sarisets, which are well made and cheap. This house confines its manufacture to these articles, and deserves credit for the perfection to which they have arrived.

The Jury make Honourable Mention of the following Exhibitors in their respective departments:—

ALIOTH, T. S., and Co., of Basle (154, Switzerland, p. 1276), for chappes and spun silks.

AMANN and EGLI, of Thorveil (153, Switzerland, p. 1276), for satinet chiné, lustrings, and gros-de-Naples.

BACHOVEN and VOLZSCHWITZ, of Zerbst (830, Prussia, p. 272), for black plush for travelling caps.

BADER BROTHERS, of Vienna (250, Austria, p. 1019), for an assortment of check and chiné silks, cravats, handkerchiefs, and scarfs.

BERT, —, of Lyons (763, France, p. 1217), for a collection of antique silks.

BERTHARD, AD., of Lyons (764, France, p. 1217), for figured umbrella and parasol silks, plaid poplins, chiné and figured silks.

BISCHOFF BROTHERS, of Basle (152, Switzerland, p. 1275-76), for plain sarinet ribbons, being specimens of a low-priced article commanding a large sale.

BOELGER, MARK, Canton of Zurich (158, Switzerland, p. 1277), for chappes and spun silks.

BRACCI-FILANDA, Al Fano (7, Rome, p. 294), for organzine.

BROOKS, THOMAS, of Spitalfields (26, p. 505), for plain silks, well made.

BUJATTI, FRANZ, of Vienna (252, Austria, p. 1019), for damask and furniture silks; also black sàgins, and some table-covers for Greece, of a peculiar style.

CALDICOTT, R. and R., of Coventry (68, p. 507), for ribbons.

CAUSSE and GARION, of Lyons (1137 France, p. 1232),

for white poil 12/13 deniers for ribbons, and for their organzines and trams, both white and yellow.

CHAMPANHET-SARGEAR, J., of Vals, near Aubenas (114, France, p. 1176), for organzine 18/21 and 26/28 deniers. (Awarded a Prize Medal by Jury of Class IV.)

CHWALLA, ANTON, of Vienna (71, Austria, p. 1010), for "drainmed" silks (à tours comptés).

DELARBRE, VICTOR, Ganges (Hérault), (1176, France, p. 1234), for white organzine 10/11, and yellow 24 deniers.

DEYDIER, PAUL, of France (1580, France, p. 1252), for organzine 18/21, and 26/28 deniers.

EYMIEU, PAUL, and SON, of Saillans (Drôme) (831, France, p. 1220), for spun silk, both weft and warp.

FABREGUE-NOURRY, FON, BARNOUTIN, and Co., of Nîmes (832, France, p. 1220), for spun silk, both weft and warp.

FORMENTO, L., of Piedmont (37, Sardinia, p. 1303), successor to Prandi, organzine 26/28 deniers.

FRIES and ZEPPEAUER, of Vienna (255, Austria, p. 1019), for damask and broché shot cotton for furniture and ecclesiastical purposes; also for figured silks in low qualities.

GANTILLON, T. E., of Lyons (1241, France, p. 1237), for his woven landscape.

GESSNER, AUGUSTE, of Wadenschweil (153, Switzerland, p. 1276), for armures, glacés, and striped and checked gros-de-Naples.

GRIEF, F. W., of Vierzehn (533, Prussia, p. 1080), for velvets, and also silks for parasols and umbrellas.

HAAS, P. and SONS, Vienna (259, Austria, p. 1019), for brocatelles of low quality. (Prize Medal awarded in Class XII.)

HORNBOETEL, C. G. and Co., of Vienna (262, Austria, p. 1019), for an assortment of plain and figured silks in considerable variety; also for figured silk handkerchiefs, terry velvets, and figured crêpe shawls.

HUBER-HORDORF, of Zurich (153, Switzerland, p. 1276), for striped and plain gros-de-Naples.

ISAAFF-UGLI, of Shemakha (207, Russia, p. 1373), for plain and striped goods made from Caucasian silk. Though deficient in quality and brilliancy, the low prices of these goods secure an extensive consumption.

JACOBI and BERING, of Crefeld (524, Prussia, p. 1080), for specimens of parasol silks.

KATHEL JOHN, of Crefeld (525, Prussia, p. 1080), for chiné and figured silks in low qualities.

KNORR, F., of Zweybrücken (38, Bavaria, p. 1100), for silk plush for hats.

KOSTNER, ALBERT, of Vienna, Manufacturer (264, Austria, p. 1019), for an assortment of brocaded silks.

KRICKE, ERNEST, Vienna (263, Austria, p. 1019), for figured silks for ecclesiastical purposes. (Honourable Mention awarded in Class XIX.)

LATTEFF, N., of Moscow (371, Russia, p. 1384), for plain, checked, striped chiné, and figured silks.

LAVERNIER and MATHIEU, of Uzès (1298, France, p. 1239), for poil or tram singles of 90 deniers for gaze à bluter and crêpe-de Chine, and for organzine 18/20 and 26/28 deniers.

LOKTEFF, J., of Moscow (204, Russia, p. 1373), for ribbons for orders of knighthood, &c., plush, vestings in gros-grains, and neckerchiefs.

MARTEL, GÉOFFROY, and VALENSOT, of Lyons (921, France, p. 1224), for an assortment of figured and broché silk cravats.

MEHFREDI, ARMENTARIO, of Rome, for organzine.

MÉJEAN, A., Lyons (1353, France, p. 1241), for organzine 24/26 and 26/28, and grenadine for lace.

MEYER and ENGELMANN, of Crefeld (582, Prussia, p. 1083), for parasol silks, cravats, shawls, and vestings.

MEYER BROTHERS, of Zurich (227, Switzerland, p. 1281), for handkerchiefs, marceline, and flounce brochés, marceline jaspé, &c.

MAX MEYER, and Co., of Berlin (133, Prussia, p. 1055), for plush for vestings and caps. (Awarded in Class XV.)

NEVIANDT and PFLEIDERER, of Mottmann (523, Prussia, p. 1080), for cravats and handkerchiefs in low qualities.

PFFENNINGERBERGER, JOSEPH, Vienna (248, Austria, p. 1019), for ribbons suited for the use of the country districts of Austria, being low in quality, and cheap at the prices quoted.

**PREISWEGER, D. & Co.**, of Bâle (152, Switzerland, p. 1275), for ribbons.

**REGARD BROTHERS**, of Darbres (1426, France, p. 1244), for white organzine, 32/24 deniers for ribbons. (Prize Medal awarded in Class IV. for raw silk.)

**ROSSI, G. M.**, of Sondrio (88, Austria, p. 1012), for trams and organzines.

**RYHNER and SONS**, of Bâle (161, Switzerland, p. 1277), for chappes and spun silks.

**SAUVAGE, R. and Co.**, of Lyons (1472, France, p. 1246), for moiré silks, armures, and taffetas.

**SCHIFFER, CARL**, of Vienna (269, Austria, p. 1020), for black plush for hats.

**SIMON, H.**, of Zweybrücken (37, Bavaria, p. 1100), for silk plush for hats.

**SITOFF BROTHERS**, of Moscow (202, Russia, p. 1373), for an assortment of silver-gilt fringes, braidings, and wire thread, and samples of brocade.

**SOPER, HENRY**, of Spitalfields (29, p. 505), for an assortment of parasol silks.

**STEINER, G., and SONS**, of Bergamo (87, Austria, p. 1012), for trams 20/30, and organzine 22/24, and 28/30 deniers.

**STIEFF and HARRAS**, of Potsdam (161, Prussia, p. 1057), for vestings and fancy cravats. (Prize Medal awarded in Class XV.)

**STILWELL and SON**, of Spitalfields, London (7, p. 504), for damask for furniture.

**THEVENET, RAFFIN, and ROUX**, of Lyons (1500, France, p. 1248), for a collection of rich rep silks and chiné shawls, and crêpe-de-Chiné shawls.

**THIBERT and ADAM**, of Metz, Moselle (1037, France, p. 1228), for an assortment of black silk plush for hats.

**THOMAS BROTHERS**, of Avignon (1040, France, p. 1228), for florences of various shades.

**TROCCON, A.**, of Lyons (1511, France, p. 1248), for a few silk shawls, and an assortment of silks for cravats.

**VALANSOT, M.**, Lyons (921, France, p. 1224), for terry velvets and plushes for bonnets.

**VANNER and SON, J.**, of Spitalfields, London (28, p. 505), for an assortment of parasol silks.

**VON DER MUEHL BROTHERS**, of Basle (162, Switzerland, p. 1277), for glacé gros-de-Naples in four qualities.

**WASHINGTON and DAVIS**, of London (8, p. 504) for plain and figured plushes for vestings, in great variety.

**WILSON and Co.**, of London (10, p. 504), for silk plush for hats.

**WIRZ and Co.**, of Zurich (153, Switzerland, p. 1276), for satiné and black gros-de-Naples.

**ZALOCHIN**, of Moscow (209, Russia, p. 1373), for gros-de-Naples, glacé, and checked moiré, and satin.

*London, August 1851.*

THOMAS WINKWORTH, REPORTER.

## CLASS XIV.

## REPORT ON MANUFACTURES FROM FLAX AND HEMP.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

## Jury.

COUNT FRANZ ERNST VAN HARRACH, *Chairman*, Austria; Chamberlain of His Imperial Majesty, President of Bohemian Society of Arts and Manufactures, Prague.

CHARLES TEE, *Deputy Chairman*, Pindar Oak, Burnley; Manufacturer.

WILLIAM CHARLEY, *Joint Reporter*, Seynour Hill, Belfast; Bleacher.

GRENIER LEVYRE, *Joint Reporter*, Belgium; Member of Senate, President of Chamber of Commerce, Ghent.

LEGENTIL, France; President of Chamber of Commerce, Paris, and of Central Jury, &c.

JOHN McMASTER, Guilford, Banbridge, Ireland; Manufacturer.

JOHN MOIR, Dundee; Manufacturer.

CARL NOBACK, N. Germany; German Commissioner.

ALEXANDER SCHERER, Russia; of the Ministry of Finance.

JOHN WILKINSON, J. P., Leeds; Flax Spinner.

BEFORE proceeding to describe the various flaxen products brought under our notice, we wish to offer a few observations on the progress and position of this important branch of manufacture. We shall, however, confine our remarks to those portions of it which are in some way exemplified by the objects collected in the Exhibition from the manufacturing countries of the world; as, in a Report like the present, a great accumulation of statistical details would be out of place, even were we prepared to offer such.

In consequence of the great antiquity of the Egyptian nation, we shall first call attention to the specimens of linen cloth sent from that country. These are in many respects much surpassed by the European manufacture. It may, however, be interesting to remark, that the first mention of linen in the ancient chronicles of the Jews certainly alludes to the productions of Egypt or some adjoining country. The Jewish priesthood were directed to use "linen garments and clothes of service;" and linen has been so generally looked upon as emblematic of purity, that it is still considered becoming in the costume of ministers, and in the services of the Christian churches.

From the Asiatic continent we have some specimens of cloth made from "*China grass*." This article is no doubt, in its essential qualities and uses, a species of flax, and therefore properly comes under our notice. It has been produced for many years by the industrious and ingenious people of China. We have remarked that in the coarse kinds of cloth made from it, the fibre appears to be *split into lengths*, and attached to each other at the smaller ends. In this simple state the pieces are put together with great dexterity. This is an interesting example of the position of this manufacture amongst one of the most ancient nations of the world.

Beside the coarser kinds of cloth, there are exhibited some beautiful handkerchiefs and other fine linens made from this material. At the present day "*China grass*" is occasionally used in making coloured fabrics, combined with other substances, such as silk and cotton; and from the peculiar brilliancy of the fibre it shows to much advantage in this way. It has not as yet entered into extensive use for plain goods; but some very meritorious attempts to ascertain its utility for that purpose have been made, and are still in progress.—(See pp. 370, 371.)

Among the continental nations of Europe, the northern have long been celebrated for the production of flax and its manufactures; Flanders being especially distinguished for the beauty of its fine goods, and Russia and Germany for the strength and durability of their heavy and other linens.

It is a remarkable fact, that so long as hand-spinning was the only known way of producing yarn, Great Britain

and Ireland were not much noted for the manufacture of linens. The wonderful change, however, wrought by the invention of the "*spinning jenny*," and its application to cotton machinery, speedily led to the development of the same principle in making mill-spun yarn from flax and hemp.

The immense and cheap supply of coal possessed by Great Britain, and the consequent facility in producing steam-power, combined with the privilege of first applying spinning by machinery to any great extent, has given her considerable advantage in the production of many descriptions of mill-spun yarns and manufactured goods. Lately this system is becoming more general on the Continent, although there has been for a long time a strong prejudice in favour of hand-spun yarn, especially in Flanders. This latter country (comprising portions of Belgium and France) has long been celebrated for the production of the finest kind of flax, and the superior texture of its hand-spun yarns. These latter require most careful and skilful manipulation, more particularly in the exceedingly fine description used in making the beautiful lawns and handkerchiefs of Cambray and Valenciennes. Ireland is producing, very extensively, both lawns and handkerchiefs, more distinguished, without doubt, in the lower and middle-priced qualities for general consumption than in the extremely fine goods. The same country has now for many years enjoyed a high and merited reputation for its linen manufactures, and supplies large quantities of the usual kinds to the different markets of the world. Scotland is pre-eminent in low-priced goods, of the qualities extensively used at home and abroad. The principle of weaving by power-loom appears to be coming into very general use in that country, and also on the Continent, as will be found by inspecting our Report further on.

The Jacquard loom is now much used in making damasks, and has tended to improve, in many respects, the manufacture of that article, both in the British dominions and on the Continent.

England produces a large quantity of mill-spun yarn from flax. Although her attention is more directed to the manufacture of cotton, she has contributed heavy linens, which, for texture and durability, are deservedly celebrated.

For the better elucidation of our decisions, we have divided our remarks on this Class into two principal departments, viz., 1st, *The prepared fibre and spun or twisted fabrics*, such as yarn, threads, and cordage; and, 2ndly, *The woven fabrics* of all kinds.

We have also divided these into minor sections, keeping, as near as possible, to the printed form of classification issued by the Royal Commissioners for the guidance

of the Juries. As a general rule, we have endeavoured to abstain from mentioning any person more than once in the Report; but there are a few cases where such persons deserve special mention in more than one of the subdivisions or minor sections. Some of their productions might be overlooked if all were mentioned together, and therefore we have occasionally noticed such cases twice.

We shall now proceed to detail the results of our examination.

### I. FLAXEN FIBRE.

In the specimens of prepared flaxen fibre the Jury did not observe anything worthy of very particular comment, or any feature exhibiting a decided improvement in the management of flax for manufacturing purposes. Honourable Mention, however, is made of two Exhibitors:—

DESMEDT and Co., Zele, East Flanders, Belgium (104, Belgium, p. 1154); and LOUIS DUMORTIER, of Bousbecque, near Lille Nord, France (177, France, p. 1182).

There are other samples of Flemish flax which are meritorious on account of their extreme fineness.

The Jury regret that the specimens of good flax from Ireland are so few in number. Those exhibited by Messrs. BERNARD and Co. of Belfast, and rated on Schenck's patent hot-water steeping process in sixty hours, are the best samples; and those by GATLEY, of Coleraine, rated on the *old cold-water* principle, are good specimens of the material prepared in that way. Both are worthy of commendation, and the Jury make Honourable Mention of them. [See "Royal Belfast Flax Improvement Society:" 106, p. 203.\*]

The particular attention of the Jury was directed to the specimens of English flax, as illustrating the successful growth of that useful and valuable plant by some of the agriculturists of this country.

The samples exhibited by Messrs. HIVES and ATKINSON, of Leeds (45, Class IV. p. 198\*), and grown by Mr. WARNES, of Trimmingham, Norfolk, possess a large proportion of the necessary qualities of perfect flax, and are equal, in point of quality and strength, to any the Jury met with of similar fineness. The dressed line, with the yarns from it, are excellent, and run up to a tolerable degree of fineness.

The specimens exhibited by Messrs. CARON, NELSON, and Co., of Selby (46, Class IV., p. 198\*), are also very good, the flaxen fibre being evidently well rated, scutched, and put out of hand. The quality is sound, tough, and good. Great credit is due to both these firms for the pains they have taken to bring forward such meritorious specimens of English-grown flax.

The Jury have also to notice that an excellent assortment of prepared flax, of various qualities, has been sent from Russia; but in comparing these with other specimens, the Jury did not observe anything worthy of special remark.

Before quitting the department of flaxen fibre, the Jury desire to report that as it was questionable whether the preparation of flax by the method of M. CLAUSSEN (Cl. IV., p. 202\*-3\*) should properly come under their cognizance, they have not pronounced any judgment on the merits of this novelty. After being disengaged from the flax straw, it may be said to become by M. Clausen's process "cotton," in all its essential qualities, and is intended to be manufactured by cotton machinery, and to compete with that material. The Jury, therefore, do not feel competent to venture an opinion as to its practical utility and value.

#### *China Grass.*

\*Among the specimens shown of the different stages of preparation, dressing, and manufacture of "China grass," the Jury consider the series exhibited by Messrs. MARSHALL and Co., of Leeds (Class IV., p. 199\*), the most suitable for manufacturing purposes. This house is deserving of great commendation, for the trouble and expense it has incurred in testing the utility of this material.

#### *Yarns.*

In mill-spun yarns there appears to be little competition. The yarns exhibited by Messrs. HIVES and ATKINSON, of

Leeds, and spun from the flax grown by Mr. WARNES (*id. supra*), as already noticed, are superior in quality and spinning, without reference to price. They consist of from 40 to 200 leas line, and are, in all respects, good in quality, fully confirming the opinion already expressed of this flax.

Ireland produces a great quantity of flax yarns, but is not adequately represented in this department. There are a few specimens from Scotland, of fair quality.

In the exhibition of hand-spun yarns there is a great amount of excellence displayed in the various specimens, more particularly in those from Belgium. The samples shown by Messrs. BERTHELOT and BONTÉ, of Cambrai (p. 1158), are surprisingly fine, perfect, and beautiful, being up to 1200's warp and 1600's weft yarn, and are certainly equal, if not superior, to anything of the kind hitherto produced. The specimens from Ireland are also very creditable; that spun by JANE MAGILL, 84 years of age, being the finest (760 leas), and that by ANN HARVEY (about 600 leas), being the most perfect in quality and spinning (No. 106, p. 203\* Class IV.). The Jury recommend the award of money premiums to these individuals, as, from their lowly condition, this will be the best and most useful recognition of their skill.

The yarns from the HEEPEN SPINNING-SCHOOL, Bielefeld (546, Zollverein, p. 1081), are also very excellent, considering the youth of the spinners. One sample produced by a little girl of 10 years old, is very fine, and exceedingly well spun out of a weak material. Another sample, by a child 8 years of age, is very good, but not quite so perfect. The Jury consider the former of these a proper subject for pecuniary reward, and have recommended that, and the two previously-noted cases, for this distinction.

#### *Linon Lacing Threads.*

In the samples of linen threads, there is such varied and general merit, that the Jury found it exceedingly difficult to draw any marked distinction as regards superiority. Those exhibited by Messrs. MARSHALL and Co., of LEEDS, (No. 26, p. 511) are found to be the most perfect as regards evenness of spinning, particularly in the fine numbers; and the Jury desire to state that the Prize Medal already awarded to this house for examples of China grass, is intended also to mark the high merit of the threads exhibited, which would certainly have received a Prize Medal, if the award had not been already made on another ground.

In shoe threads, those exhibited by Messrs. W. B. HOLDSWORTH and Co., Leeds (53, p. 512), are the best; and the samples shown by Messrs. FINLAYSON, ROUSEFIELD, and Co., Glasgow (48, p. 512), and Messrs. TITLEY, TATHAM, and WALKER, Leeds (51, p. 512), are of good quality. The two former firms having been awarded Medals on other grounds, it is sufficient to record this opinion of the shoe threads.

#### *Cordage, &c.*

The Jury found the collection of ropes for marine and other purposes, with cord, twine, &c., very limited in extent; and from the few goods exhibited it is impossible to have a precise idea of the progress made of late years in these manufactures. They found but one exhibitor worthy of the honour of a Medal.

### II. WOVEN FABRICS.

In the second department of flaxen products, namely "woven fabrics" of all kinds, the following countries have contributed:—England, Scotland, and Ireland, France, Belgium, Russia, North Germany, Spain, Portugal, China, and Egypt.

From the British dominions there is about one-half the number of the entire exhibitors and goods.

#### (a) *Canvas, Sailcloth, Sacking, Carpeting, &c.*

Some goods have been exhibited by several manufacturers in conjunction, from the town of Bridport, and the district of Crewkerne, Somersetshire (the latter generally styled Coker canvas), all of excellent quality. The Jury being of opinion, in such cases, that Medals could not be

awarded, think that Particular and Honourable Mention is due to them.

In this subdivision the Jury have found great excellence, the exhibition of the various countries being highly creditable to the manufacturers engaged in this branch of industry.

(b) *Woven Fabrics, heavy and low-priced Linens; Huckabacks, Crash, Duck, Ticks; Low Sheetings, Brown and Fancy-striped ditto, Dowlas, Holland, Low Brown Linens, Osnaburys, &c.*

The goods of this subdivision are of very extensive consumption, and their chief characteristic, especially in the Scotch and Irish, is lowness of price; those exhibited by the manufacturers of Barnsley are of very superior quality for family use, and consist of an extensive assortment of ducks and drabbets, ticks, damasks, hucks, &c.; being an exposition of the peculiar manufacture of that town and district. The Jury were much pleased with the general excellence of these goods.

(c) *Plain Linen of all widths, bleached or unbleached.*

In this subdivision the exhibition is very extensive and varied, and the goods generally display much care and skill of manufacture, particularly the finer descriptions.

COUNT HARRACH, of Janowitz, Moravia (285, Austria, p. 1020), has exhibited hand-spun bleached linen and bleached yarn of very fair quality. Also fancy damasks for lining carriages and for covering furniture, made in imitation of silk.

These latter the Jury consider worthy of special notice; but Count Harrach, being a member of the Jury (and also Chairman), cannot compete for any Medal. The skill and merit, however, in producing these goods, deserve high commendation.

THE ROYAL BELFAST FLAX IMPROVEMENT SOCIETY (p. 203\*), have exhibited a very interesting series of patterns of the flaxen manufactures, characteristic of that country; comprising sucking, huckabacks, drills, diapers, ticks, lincens, lawns, hollands, &c.

WHYUNE, a merchant of Canton, China (1419), has shown, in the department allotted to that nation, a variety of cloths and handkerchiefs made from China grass. Honourable Mention is due to him, as the only exhibitor of this peculiar article from that country.

Some samples have also been contributed by MARSHALL and Co., of Leeds (55, Class IV., p. 199\*), of cloth from this material. In speaking of yarns, allusion has already been made to the merit they deserve in improving and developing the manufacture of this material.

WILFORD, JOHN, & SONS, of Northallerton (42, p. 512), have sent, with their other goods, a piece of sheeting made from China grass, and bleached in Ireland. This is also worthy of notice.

(d) *Drills, Damasks, and Twilled Linens of all kinds.*

In this subdivision the Jury have had much difficulty in discriminating, the competition being so close and the excellence of the goods so general.

The town of Barnsley, as before mentioned, exhibits very deserving specimens of its manufacture in this subdivision. And the names of those manufacturers who have contributed to this Exposition will be found duly classified amongst those of whom Honourable Mention has been made.

CHARLES TEE and SON, of that town (87, p. 512), have exhibited a varied and beautiful assortment of plain and fancy cloths for waistcoats and dresses of excellent quality, and made with great taste in the patterns. The Jury would have awarded a Medal to these goods, but Mr. TEE, senior, being a member of this Jury, cannot enter into competition for such a distinction. Honourable and Special Mention is therefore due.

(e) *Cambrics, Lawns, and Printed Linens for Dresses, &c.*

This subdivision is the last of Class XIV. • •

*Conclusion.*—In conclusion, the Jury wish to remark, that the management of flax and its products involves a great amount of skill and labour, from the sowing of the

seed till the completion of the manufactured articles; and they have to express their satisfaction at the excellence of the textile fabrics contributed by the various countries,—an excellence so general, as to render their task of selecting the best, in many cases, exceedingly difficult. Bearing in mind the wish of the Royal Commissioners, they have sought to reward superior merit wherever such has appeared evident. In cases of very close and doubtful competition, they have given Medals, or Honourable Mention, to each of the parties. The Jury have avoided, as much as possible, invidious comparisons between nations, or individuals, feeling satisfied the public and business-men will discriminate in this respect for themselves. The remarks in this Report, as before mentioned, are confined to subjects brought up under their notice, in examining the collection of goods in the Building.

The Jury have decided on not recommending any Council Medals in this Class, as they considered that such a distinction was intended to mark either discovery or invention, or such a new application of known materials as might tend to important results in the department of industry to which it was applied, and not to perfection of manufacture or taste.

It is satisfactory to the Jury to be able to state, that there has been no disagreement amongst the members in making their decisions. This fact not only confirms them in the justice of their awards, but will tend to strengthen the public reliance in their impartiality.

The office of Judge or Juror is at all times one of great responsibility, and on the present occasion more particularly so, as the whole world is waiting their decisions. The members of the Jury are sensible of the confidence placed in them, in being selected for such an honourable task, and they have endeavoured faithfully to discharge the important and onerous duties entrusted to them.

The Jury award Prize Medals to the following exhibitors in the various subdivisions:—

IMPERIAL ALEXANDROVSK MANUFACTORY, Russia, (19A, Russia, p. 1366), for canvas of superior quality.

ANDREWS, MICHAEL, Ardoyne, Belfast, Ireland (5, p. 510), for excellence in double damask table-cloths and napkins.

BERTHELOT and MONTÉ, of Cambrai, Belgium (216, Belgium, p. 1158), for superior excellence and fineness in hand-spun flax yarn.

BEVER'S WIDOW & Co., Zittau (51, Saxony, p. 1107), for superiority of design in damask cloths and napkins.

BIRRELL, DAVID, Dunfermline (27, p. 511), for damask table-cloths and napkins of superior quality, fineness, and design.

BOLLENIUS and NOLTE, Bielefeld (562, Prussia, p. 1052), for fine lincens.

BONIFACE and SON, of Cambray (32, France, p. 1172), for cambrics of exceedingly fine and beautiful finish.

CLIBBORN, HILL, & Co., Banbridge, Ireland (20, p. 511), for diapers. An excellent assortment, bleached.

COOREMAN, A. J., Rebecq, Belgium (212, Belgium, p. 1158), for the finest and most perfect lace thread made from hand-spun yarns.

CUTLSON, JAMES, & Co., Lisburn, Ireland (92, p. 516), for an extensive and admirable exhibition of fine, well-made damask table-cloths and napkins.

COX BROTHERS, Dundee (63, p. 513), for low-priced striped bedding and hessians.

CUMONT-DECLERQ, Alost, Belgium (235, Belgium, p. 1158), for superiority in the colour of his linen threads.

DAUTREMER and Co., of Lille (Nord) France (137, France, p. 1178), for excellent quality and evenly-spun flax-yarns, from 100 to 320 leas.

DECOCK-WATTRELOT and BAUDOUIN, Roulers, Belgium (221, Belgium, p. 1158), for fine lincens. A good variety.

EICKHOFF, ANTON, Heirs of, Warendorf (549, Prussia, p. 1081), for neatness of design in his exhibition of damasks, and goodness of colour in his lincens.

FERROL, Royal Manufactory of Isabella II. at, Spain (193, Spain, p. 1341), for canvas of superior quality.

FINLAYSON, BOWSFIELD, & Co., Glasgow (48, p. 512), for the strong threads exhibited in the coarse and

middle sizes, and for the great taste and neatness with which they are got up.

FRASER, DOUGLAS, Arbroath (79, p. 515), for canvas of superior quality, made by steam-power looms.

GRASSOT and Co., Lyons (526, France, p. 1204), for superior style of damasks, and excellence in carrying out the patterns.

HARO, E. F., 18 Rue des Petit Augustins, Paris (866, France, p. 1221), for the extraordinary dimensions and excellence of canvas for historical painting.

HENNING, JOHN, Waringstown, Ireland (16, p. 510), for damask table-cloths of superior patterns and quality, bleached, brown, and mixed colours.

HIVES and ATKINSON, of Leeds (45, Class IV., p. 198\*), for good quality in mill and spun yarns.

HOLDSWORTH, W. B., and Co., Leeds (53, p. 512), for the superior style and colour of their satin-finish linen threads, being the best examples of threads prepared by that method.

KIRK, WILLIAM, & SON, Armagh, Ireland (10, p. 510), for brown linens, of low description and prices; Hollands, brown, black, and slate-coloured, &c.

KRAMSTA, C. G., and Sons, Freyburg, Silesia (128, Prussia, p. 1155), for a good assortment of bleached platillas of export quality.

KUMS, E., Antwerp (468, Belgium, p. 1166), for variety of low heavy goods, comprising canvas, imitation Russia sheeting, &c.

LAING, J. and A., Dundee (63, p. 513), for ducks, imitation Russian sheetings, striped ditto, &c., of excellent quality.

LAWSON, ALEXANDER, Fifeshire (63, p. 513), for a large and low-priced variety of dowlas, lucks, sheeting, window-blinds, &c.

MC CAY, THOMAS, Dromore, Ireland (19, p. 511), for an exceedingly fine piece of fronting linen, made of mill-spun warp and hand-spun weft, exhibited brown.

MALO-DICKSON and Co., Dunkirk, France (320, France, p. 1192), for canvas of superior quality.

MC MURRAY, THOMAS, and Co., Dromore (25, p. 511), for a superior assortment of fine linens, bleached.

MARSHALL and Co., of Leeds (55, Class IV., p. 199\*), for their examples of the preparation of "China grass" for the purposes of manufacture.

MERLIE-LEFEVRE & Co., Havre (926, France, p. 1224), for a varied assortment of cordage of remarkably good character.

MESTIVIER and HAMOIR, Valenciennes, France (636, France, p. 1208), for the great excellence and superiority, exceedingly fine and very beautiful finish, of their assortments of cambrics, plain and bordered.

MILVAIN and HARRORD, Newcastle-on-Tyne (71, p. 514), for canvas of superior quality, made with bands, which add to the strength.

MORMAN-VANLAERE, J., Ghent (231, Belgium, p. 1158), for variety of canvas of tow, flax, and hemp, and very broad coverings for railway waggons.

PARENTIER, P., Isighem, Belgium (222, Belgium, p. 1158), for fine linens of superior quality, exhibited brown, and made from mill-spun yarn of Liege. Also a small assortment of handkerchiefs, very well manufactured.

PELDRIANS' HEISS, Hohenelbe, Bohemia (288, Austria, p. 1021), for fine linen, of hand-spun yarn.

RICHARDSON, I. N., Sons, & OWDEN, Belfast (7, p. 510), for a superior assortment of light shirting linens for export, bleached.

SADLER, FENTON, and Co., Belfast, Ireland (18, p. 510-11), for a superior assortment of heavy shirting linens, for home trade, bleached.

SCHEVE BROTHERS, Lille, Nord, France (1007, France, p. 1227), for damasks, including their yarns and power-loom goods.

SHEFTON, J. and SON, Dundee (63, p. 513), for dowlas, crequillas, creag, &c., of light and low-priced quality for export.

WENTIG, CHE. DAV., and Sons, Gross-Schönau, near Zittau and Leipsic (53, Saxony, p. 1107), for damask table-cloths and napkins, of superior neatness in design and good quality.

WARNES, JOHN, of Trimmingham, Norfolk, for the

growth and preparation of the flax exhibited by Messrs. Hives and Atkinson, of Leeds (45, Class IV. p. 198\*).

WESTERMANN, A. II., and Co., Bielefeld, Westphalia (543, Prussia, p. 1081), for linens, well bleached.

WILFORD, JOHN, and Sons, Northallerton, Yorkshire (42, p. 512), for plain and fancy drills of very superior quality of styles.

The Jury make Honourable Mention of the following Exhibitors:—

AMEYE-BERTE Ghent (209, Belgium, p. 1158), for waggon-coverings and other heavy goods made by power-loom.

BECK and Sons, and other exhibitors, Switzerland (163, Switzerland, p. 1277), for damasks and drills of fair quality.

BECK and SON, Courtrai, Belgium (324, Belgium, p. 1161), for a very fine piece of linen of hand-spun yarn, bleached. (Prize Medal awarded in Class XIX.)

BELL, T., and Co., Lurgan, Ireland (6, p. 510), for a good assortment of cambric handkerchiefs.

BERNARD and Co., Belfast, Ireland, for good hot-water steeped flax. (203\*.)

BEVERIDGE, ERSKINE, of Dunfermline (29, p. 511), for damasks. (He also exhibits a good variety of stair and floor covering, &c.)

BOLLENIUS and NOLTE, Bielefeld, Germany (562, Prussia, p. 1082), for evenly-spun flax yarns, 480's being the finest.

BRUZZHIN, ALEXANDER, Kaluga (216, Russia, p. 1373), for good canvas.

BURBACH BROTHERS, and Co., Horsfelgii, (799, Prussia, p. 1094), for water-pipes of hemp, without seams.

CANTER, J., Barnsley (36, p. 511), for ducks, drab-bets, &c.

CARTER BROTHERS, Barnsley (36, p. 511), for ducks, drab-bets, &c.

CARTHAGENA, Royal Arsenal, Spain (191, Spain), for excellence of cordage.

CATOR, NELSON, and Co., of Selby (46, Class IV. p. 198\*), for the excellence of their flaxen fibre. (Honourable mention awarded in Class IV.)

CORRY, BLAIN, and Co., Belfast (24, p. 511), for good damasks, made with power-loom; and a beautiful and novel design, on paper, for a table-cloth, not yet executed in cloth.

COULSON, WILLIAM, Lisburn, Ireland (93, p. 516), for a very fine damask cloth.

DAUDRÉ, A., St. Quentin (1170, France, p. 1233), for good damasks.

DÉBOURAIL, HENRI, Courtrai (239, Belgium, p. 1158), for good drills and other articles.

DESMEDET and Co., Zele, East Flanders, Belgium (104, Belgium, p. 1154), for specimens of Flemish flax, being the most perfect from Belgium. (Prize Medal awarded in Class IV.)

DORRELAERE-HULIN, Ghent (208, Belgium, p. 1158), for brown hand-spun sheetings, imitation Russian ditto, of good quality.

DOMMER, T., Alost, Belgium (233, Belgium, p. 1158), for some good cambric handkerchiefs, white and printed, and a variety of other linen articles.

DON, W. & J., and Co., Forfar and Dundee (63, p. 513), for brown sheetings and Osnaburghs of good quality.

DON BROTHERS and Co., Forfar and Dundee (63, p. 513), for brown sheetings and Osnaburghs of good quality.

DOUMORTIER, LOUIS, of Bousbecque, near Lille, Nord, France (177, France, p. 1182), for the best and most perfect specimens of scutched flax, rated and prepared on the Courtrai system. (Prize Medal awarded in Class IV.)

FASSON, ALEXANDER, Dundee (63, p. 513), for sail-cloth and sacking of tow, hemp and jute.

EDINBURGH ROPE AND SAIL-CLOTH COMPANY, Edinburgh (p. 513), for good canvas.

ELMENDORF, E. F., (470, Prussia, p. 1078), for specimens of good middle-sized yarns.

FERIE, WENZEL, Bohemia (284, Austria, p. 1020), for lawns of fine quality and colour.

FLETCHER, II. T. Barnsley (36, p. 511), for ducks, drab-bets, &c.

GAILLEY, D., Coleraine (106, Class IV., p. 203\*), for flax steeped upon the cold-water system.

GHEENT LINEN COMPANY, of Belgium (230, Belgium, p. 1158), for the heavier examples of tow yarns.

GODARD and BONTEMPS, Valenciennes and Paris (240, France, p. 1188), for a good variety of white and printed fine cambrics.

GOENS, L. J., Termonde (237, Belgium, p. 1158), for general excellence of cordage.

GUYNET and BECQUET, of Cambrai and Paris (254, France, p. 1189), for fine cambrics.

HATTERSLEY, PARKINSON, & Co., Barnsley (36, p. 511), for ducks, drabnets, &c.

HAXWORTH and CARNLEY, Barnsley (36, p. 511), for ducks, drabnets, &c.

HENNING, JOHN, Waringstown, Ireland (16, p. 510); Honourable Mention is here made, as this exhibitor is awarded a Medal for damasks, which also includes the variety of cambrics and printed goods he has exhibited in this subdivision.

HOLLOWAY, T. J., Salisbury (74, p. 515), for the general excellence of the cordage exhibited by him.

HUNT, W. and SON, of Dunfermline (28, p. 511), for good quality and designs in damasks.

JOUBERT-HONNAIRE, and Co., Angers (552, France, p. 1205), for good canvas, principally made of hemp. (Prize Medal awarded in Class IV.)

JACKSON and MATTHEWMAN, Barnsley (36, p. 511), for ducks, drabnets, &c.

KAZALETT, A., St. Petersburg (102, Russia, p. 1369), for general excellence of cordage.

KIRSTEIN, C., Bielefeld (120, Prussia, p. 1055), for a good assortment of linens.

KROENIG, F. W. and SONS, of Bielefeld (556, Prussia, p. 1081), for a good assortment of linen.

LAINE-LAROCHE, and MAX-RICHARD, Angers, Maine et Loire, France (286, France, p. 1190), for dry spun-yarns made of hemp, of good material and quality. (Prize Medal awarded in Class IV.)

LANDERNEAU JOINT STOCK LINEN COMPANY, France (1019, France, p. 1227), for good canvas made from hemp.

LEADBETTER, J., and Co., Dundee (63, p. 513), for a low-priced variety of checked and striped linens.

LEGRAND, DANIEL, Avesne, Nord, France (1313, France, p. 1239), for good and fine cambric handkerchiefs.

LIESKE and HÄBLER, Gross-shandle (52, Saxony, 1107), for good damasks.

MALCOLM, J., Lurgan, Ireland (22, p. 511), for bleached lawns and handkerchiefs,—a good variety.

MENGDEN, MICHAEL VON, Russia (222, Russia, p. 1373), for good damasks.

MOORE, W. F., Isle of Man (67, p. 513-14), for good canvas.

PIGOT and NEWTON, Barnsley (36, p. 511), for ducks, drabnets, &c.

RENNY, SONS, and Co., Arbroath (81, p. 515), for good canvas.

RICHARDSON, J. and T., and Co., Springfield, Lurgan, Ireland (21, p. 511), for cambric handkerchiefs.

RICHARDSON and Co., Lisburne (23, p. 511), for excellency of bleach, shown in fine linens.

ROYAL BELFAST FLAX IMPROVEMENT SOCIETY (Class IV., 106, p. 203\*), for a very interesting series of patterns of the flaxen manufactures, characteristic of that country; comprising sacking, huckabacks, drills, diapers, ticks, linens, lawns, hollands, &c. (Council Medal awarded in Class IV.)

SCHULZE, DANIEL, Bodenteich, Lüneburgh, Hanover (6, Hanover, p. 1133), for specimens of good middle-sized yarns.

SEEMANN, C. and H., Stutgard (36, Würtemberg, p. 1117), for fine white and printed linen.

SEIGL, J., and Co., Moravia (290, Austria, p. 1021), for a good specimen of creas, bleached.

ST. BERNARD, the House of Correction, at Antwerp (226, Belgium, p. 1158), for dowlas, imitation Russia sheeting, ducks, &c.; a good variety.

TITLEY, TATHAM, and WALKER, of Leeds (51, p. 512), for excellence in colour of the linen threads.

VAN ACKERE, J. C., Courtrai (215, Belgium, p. 1158), for a very fine piece of linen of hand-spun yarn, double thread, in warp.

VAN DEN HOOGEN, T. Dortrecht, Holland (26, Netherlands, p. 1143), for general excellence of cordage.

VAN DER VOORT, H., Boxtel, Holland (45, Netherlands, p. 1144), for good damasks.

WALTON and Co., Knaresborough (38, p. 512), for sheetings and huckabacks of good quality.

WARDEN, A. J., Dundee (63, p. 513), for carpeting made of jute.

WESSEL, F. W., Bielefeld (542, Prussia, p. 1081), for a good assortment of linens.

WHITNEY, of Canton, China (p. 1419), for a variety of cloths and handkerchiefs made from China grass.

WILFORD, WILLIAM, Tamise, Belgium (211, Belgium, p. 1158), for good canvas.

WILFORD, JOHN, & SONS, of Northallerton (52, p. 512), have sent, with their other goods, a piece of sheeting made from China grass, and bleached in Ireland. This is also worthy of notice.

WILKS, JONAS, Watling-street, London (31, p. 511), comprising bleached and brown, heavy and frothing linens, huckabacks, and Russia sheetings, all of very excellent quality and style. This gentleman exhibits as a merchant; but the Jury, in accordance with the rules laid down by the Royal Commissioners, cannot award a Medal in such a case, he not being the manufacturer.

The Jury award the sum of 10*l.* each to the following subjects:—

HARVEY, ANN, Belfast, Ireland, for perfection and quality of hand-spun flax yarn. Exhibited by the Royal Flax Society of Ireland (106, Class IV., p. 203\*).

HEEPEN-SPINNING-SCHOOL, Bielefeld, Germany (546, Prussia, p. 1081), to a little girl 10 years of age, for fine and well-spun flax yarn.

MAGILL, JANE, Belfast, Ireland, for fine hand-spun flax yarn. Exhibited by the Royal Flax Society of Ireland (106, Class IV., p. 203\*).

• WILLIAM CHARLEY, }  
• GRENIER LEFEVRE, } JOINT REPORTERS.

*London, June 1851.*

## CLASS XV.

## REPORT ON MIXED FABRICS, INCLUDING SHAWLS, BUT EXCLUSIVE OF WORSTED GOODS.

[ The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE. ]

*Jury.*

CHARLES VAN HOEGAERDEN, *Chairman*, Belgium; Merchant, Member of Chamber of Commerce, Brussels.  
 JOHN R. LAVANCHY, *Deputy Chairman*, 6 New Burlington Street; Silk Mercer.  
 W. CLABURN, Norwich; Manufacturer.  
 MAXIME GAUSSEN, France; Member of the Central Jury.  
 DAVID KEMP, Glasgow; Shawl Merchant.  
 N. KINGSBURY, United States; Manufacturer.  
 JOHN MORGAN, Grenlaw, Paisley; Manufacturer.  
 WILLIAM PRINSEP, *Reporter*, 30 Gloucester Gardens.  
 TITUS SAIT, J. P., Bradford; Manufacturer.  
 FREDERICK SCHWANN, Huddersfield; Merchant.  
 JOHN H. SWIFT, United States; Merchant.  
 SIR GARDNER WILKINSON, Turkey.

*Associates.*

F. BERNVILLE, France; Spinner and Manufacturer.. (*Juror in Class XX.*)  
 GEORGE HAINS, 31 Milk Street, City; Shawl Manufacturer.

**A.—MIXED WOVEN FABRICS, OF VARIOUS MATERIALS, SHOT WITH EITHER COTTON, LINEN, WOOL, SILK, MOHAIR, OR OTHER SUBSTANCES.**

THE description given in the "Classification for the use of Juries" of the articles to come under the examination of this Class is so very miscellaneous, namely, "for dresses, damasks, aprons, shoe and boot cloths, linings, cravats, vestings, ponchos, pantaloon cloths, coatings, tweeds, quiltings, plaids, tabinets, poplins, paramattas, chalis, barèges, cashmeres, articles for furniture, shawls," that some necessity was found for drawing a line more definitely between this and Class XII., where, under the head of "Woollen and Worsted," many of the above articles would be better placed.

We have consequently confined our notice to the following articles:—Vestings, coatings, tweeds, linings, pantaloon stuffs, shoe and boot cloths, cravatings, plaids, tabinets, poplins, paramattas cashmerets, cassinets, chalis, barèges, cashmeres, shawl cloths, and Utrecht velvets.

*General Remarks.*

It is difficult to give a correct idea of the origin of many of these fabrics. Varieties of them have been made in Yorkshire, Gloucestershire, and Norfolk, from time immemorial, and are of equally ancient date in many parts of Europe. The introduction of spun silk into wool may be dated from 1685, when the revocation of the Edict of Nantes brought over to Spitalfields and to Norwich especially nearly 30,000 artisans from Paris and Lyons, who established these manufactures in England. We find that the importations of silk into Ireland in that year were of 80,000*l.* value. Tabinets or poplins have been produced in Ireland ever since 1771. Novelties are being constantly introduced, both in style and texture, as well as in new combinations of materials, and many most valuable experiments of this character have been adopted, particularly within the last ten years. We may notice two articles in particular, which have become of great importance to this class of manufactures, viz., alpaca and mohair. The former is the wool or hair of an animal of the llama tribe from the region of Peru; the latter, that of a goat peculiar to Asia Minor: and some idea of the rapid development of such novelties may be formed from the following returns of imports, viz.,—Of alpaca wool, from 1836 to 1840, 7000 bales per annum; from 1841 to 1845, 13,000 bales per annum; from 1846 to 1850,

20,000 bales per annum. Of mohair, in 1841, 5,621 bales; in 1850, 12,884 bales.

We believe that to England must be accorded the chief credit of searching for and adopting most of the new and important materials which are every year being introduced into these manufactures, tending naturally to increase the value of the trade: she also takes the lead in the quantity of production. France, ever ready to adopt and improve, produces very largely the same articles, and is peculiarly successful in the finer and richer descriptions, where delicacy of design and colour is most favourably applied; and had she equal facility with England in sending her productions into foreign markets, the development of her medium classes of these goods would have been more complete. Austria has made very great progress within the last ten years in these fabrics; her materials are excellent, and ably put together; and she presents them at low price, for a large internal consumption. Bohemia, in particular, supplies tissues of a quality that bears the stamp of decided progress. Labour in these countries is extremely cheap, and the artisans are intelligent, and if the progress now apparent continues with increased energy for the coming ten years, their productions may vie, particularly in price, with those of all Europe; but we find no originality among them, whether of design or manufacture. Prussia and the States of the Zollverein have given valuable proofs of their powers of copying the productions of France and England. They require but the support of capital, and the encouragement of a natural taste for design, to become the producers of the best articles at low prices; for in many cases they have the raw material at hand, and they are not wanting in either energy or ingenuity to give the fullest development to such advantages. In Belgium we find proofs of a very active commerce in these fabrics, and an increasing desire to take advantage of the demand for exportation of middling and low-priced goods. The ancient excellence of the weavers of that country has not, apparently, prompted the manufacturers to keep the lead in textile fabrics, either in character or quality. Their produce is very extensive, both for the home and foreign demand, and they appear to prefer leading purchasers to their stores by cheapness and goodness of manufacture, rather than by the attraction of superior excellence or novelty. Portugal has exhibited some good copies of French and English fabrics, which give fair promise of excellence. Egypt has contributed some specimens of its early essays

in these fabrics; but as they are chiefly the produce of artisans of other countries, they should only be noticed as evidence of her desire to promote the industry of her population in working upon the raw materials at her command.

The peculiar feature of this manufacture is, that in most descriptions the hand-loom alone is made use of, giving employment to a vast number of persons, we may perhaps say millions; who are thus, by the various occupations connected with it, placed entirely above want.

*Particular Remarks.*

Exhibitors of various articles are in number as follows:—

|                   |           |     |
|-------------------|-----------|-----|
| From England      | - - - - - | 30  |
| Scotland          | - - - - - | 3   |
| Ireland           | - - - - - | 6   |
| France            | - - - - - | 11  |
| Zollverein States | - - - - - | 38  |
| Austria           | - - - - - | 16  |
| Belgium           | - - - - - | 13  |
| Holland           | - - - - - | 1   |
| Portugal          | - - - - - | 2   |
| Switzerland       | - - - - - | 2   |
| Total             | - - - - - | 122 |

Among whom we proceed to notice those who are most worthy of remark.

**SCHWANN, F.**, Huddersfield (115, p. 490). All his assortment of embroidered cashmeres and other descriptions are of perfect character, particularly the valentias. The designs are rich, and in good taste; and the execution such as to create regret that the names of the artisans are not recorded.

This contributor being a member of the Jury of this Class, his goods are not under consideration in competition for the reward of merit.

The Jury award Prize Medals to the following Exhibitors in this department:—

**ATKINSON, R., and Co.**, 30 College Green, Dublin (256, p. 498), for poplins of excellent quality, rich in colour, and perfect in manipulation. There are some double and triple corded, of admirable execution. The figured pieces are of good design and brilliant effect. The specimen given of their weaving, by the presence of one of their weavers, who works at an elegant loom upon a rich and elaborate design, is highly interesting and instructive.

**BOLINGBROKE, C. and F.**, Norwich (311, p. 501), for poplins, plain, striped, watered, of superior make and excellent colours; the character of their manufacture is highly meritorious.

**BROWN and FORSTER**, 5 Vigo Street, Regent Street, London (9, p. 480), for a variety of superior vestings, of cotton warp and west of wool, worked by Jacquard, in designs of excellent taste; likewise stuffs of other descriptions. Their waistcoatings of plush vagonia will be found remarkable for novelty and excellence, and as being well adapted for a large consumption.

**CATTEAUX BROTHERS**, Brussels (244, Belgium, p. 1159), for pantaloons stuffs of cotton-wool and linen with cotton. They are fabrics of good taste and extensive consumption, and highly deserving of merit for cheapness.

**CATTEAUX-GAUQUEL**, Courtray (245, Belgium, p. 1159), for fabrics of the same description, but chiefly calculated for the lower classes. A Prize Medal is awarded for goodness of texture and cheapness.

**CORNALDI, D.**, Vienna (not in the Catalogue), presents specimens of vestings of spun silk and wool, also in fine Saxon wool, figured on the Jacquard. There are some with corners embroidered on a new principle. These goods are of decided merit.

**CROCO, F.**, 163 Rue de Charonne, Paris (809, France, p. 1219), for vestings distinguished for the purity and elegance of their design, and for fineness of execution, particularly in the cashmere descriptions, attention being apparently more given to quality than to cheapness of price: his goods are of high merit.

**DAY, JOHN, and Son**, Mold Green, Huddersfield (113, p. 490), for a pantaloons stuff, warp of cotton with a west

of carded wool, crossed on one side only, of the character of cassinet. The surface of this stuff is soft to the touch, without having been sheared. This fabric is remarkable for excellence and equality of tints, difficult to accomplish.

**ECHINGER BROTHERS**, Vienna (304, Austria, p. 1022), for vestings of a strong and useful character, made with cotton, wool, and silk, of moderate price, worth about 4s. per yard; some with combination of colours.

**FASSIN, —, jun.**, Rheims (France), for a variety of excellent goods of a similar description, destined for home consumption, and got up with good taste, chiefly waistcoatings of cotton warp shot with wool and silk, also with combed wool, such as cashmere and valentias, figured with spun silk, of good design and quality. These examples are of great merit, both in execution and lowness of price.

**FURKE, R.**, Gladbach (587, Prussia, p. 1083), for a variety of superior fabrics, well coloured and of excellent materials, in several combinations of cotton, wool, and silk, for summer cloths and dresses, such as the Victoria cloths and cassinets, which deserve particular notice.

**GRABE and NEVIANDT** (591, Prussia, p. 1083), for vestings, made on the Jacquard loom, of cotton warp shot with wool, and figured in various styles; they are of superior merit.

**HAAS, PHILIPP, and SONS**, Vienna (259, Austria, p. 1019), for woollen velvet shot with cotton, of superior quality, soft in texture, and strong. Medal awarded in Class XII.

**HEYMANN, CHARLES, and Co.**, Crefeld (575, Prussia, p. 1082), for vestings, chiefly made on harnes looms, of the character of poplin, corded with cotton in weft. Some worked with gold thread have a rich effect, at a moderate price, averaging not more than 3s. 7d. Their productions are of decided merit.

**KAUFFMANN, H.**, Berlin (117, Prussia, p. 1055), for specimens of woollen velvets, of plushes of goats' hair of various descriptions, printed, and chiné, and all of high merit, fully deserving the award.

**LEAROYD, JAMES**, Huddersfield (115, p. 490), for cassinets of a very superior quality, exhibited along with the goods of Mr. Schwann: although his name does not appear as an exhibitor, he is entitled to the full credit of excellence.

**LEAROYD, W.**, Huddersfield (115, p. 490), for cassinets of a superior quality and novel make, presenting different faces of satin and cloth, where the difference of tint in dyeing is not perceptible; and other fabrics of superior merit. This manufacturer has exhibited his specimens with those of Mr. Schwann.

**LEFÈVRE-DUCATTEAU BROTHERS**, Roubaix (1300, France, p. 1239), for vestings of excellent quality, and although chiefly prepared for the middle classes, distinguished for good design and make. We noticed particularly a waistcoating of cotton warp, with west of combed wool, checked with silk. Also some valentias, figured with silk, of admirable design and fabric. Their tasteful and varied cheap goods are prepared for a very large consumption.

**LEMAIRE, DESCAMPS, and PLISSART**, Tournay (240, Belgium, p. 1158), for specimens of pantaloons stuff of linen warp and west of satiné. Those at the price of 6d. are extraordinarily cheap.

**LIENART-CHAFFAUX, Madame**, Tournay (242, Belgium, p. 1158), for specimens of pantaloons stuff of linen warp, and west of cotton satiné, well manufactured, and at the low price of 7d. and 8d. per yard.

**MARX and WIEGERT**, Berlin (113, Prussia, p. 1054), for excellence of manufacture in Utrecht velvet.

**MILNER and HALE**, Huddersfield (not in the Catalogue), for excellent cashmerettes of the kind called kersey-mere, warp of cotton and west of wool (carded merino). This stuff is milled and worked with a fluff, and is remarkable for its softness and perfection. The tints of both cotton and wool are so perfectly equalised as to be scarcely distinguishable. There is another kersey-mere warp of organzine silk and west of carded wool, equally well blended in colours, of which the feel and quality are admirable. Their merit is undoubted.

MORGENROTH and KRUGMANN, Elberfeld (532, Prussia, p. 1080), for woollen velvet, plain and figured, of a quality of distinguished merit.

MURLEY, W. J. C., Bow Churchyard, London (10, p. 486), for vestings of the character of velvet with goats' hair and cotton; cotton warp with silk weft. These are of superior character: but their vestings of linen thread and silk are truly remarkable. Their embroidered waist-coatings by the "*Saltant brocheur*," merit particular attention for excellence of workmanship. This house presents articles of high merit.

PATRIAU, CHARLES, Rheims (1380, France, p. 1242), for great variety and excellent taste in their vestings of cashmere, with cotton warp and weft of silk and wool; those also of woollen plush, plain and figured, are particularly deserving of notice. The poplin vestings are likewise of distinguished perfection. This house has produced at Rheims a new fabric called *piqué*. They employ a great number of artisans, and supply largely for exportation showy and cheap goods as well as those of superior qualities, which are eagerly demanded for home consumption. The superior and pre-eminent character of their manufactures entitles them to the very highest consideration, and in the opinion of the Jury they fully deserved the award of the Council Medal; but this was not confirmed by the Council of Chairmen.

PFERDMENGES and KLEINJUNG, Vierzehn (573, Prussia, p. 1082), for an excellent description of vestings of cotton warp, with weft of carded and combed wool, worked with silk cheeks, of varied and good designs.

PIM BROTHERS and Co., Dublin (255, p. 498), for excellent specimens of poplin got up with great carefulness and evenness of make. There are some on the Jacquard, figured of single colour, worthy of particular notice, and one especially woven with four colours highly deserving of merit for perfection of make and design.

ROCKSTROM, H., Vienna (306, Austria, p. 1022), for good specimens of waistcoatings of cotton and wool, with the corners of the waistcoats figured by the Jacquard. They are sold at the low price of 1s. 7d., and, in this respect, the merit of the exhibitor entitles him to reward.

STIEFF and HARRASS, Potsdam (161, Prussia, p. 1057), for a variety of superior vestings of silk warp and cotton weft, figured with silk, by the Jacquard loom, with good effect, at very moderate prices. They also show two pictures of Jacquard imitations of engravings. Their productions are of high merit.

TAYLOR, J., and SON, Newsome, Huddersfield (111, p. 490), for vestings of great variety and superior make. The cashmeres are of good taste and high merit. There is among them a novelty of good invention, being a variegated cloth of cotton warp, figured and shot with goats' hair, styled *Tigré*. The fabrics of this house are of the highest merit, and in the opinion of the Jury entitled to the award of a Council Medal; but this was not confirmed by the Council of Chairmen.

TEE and SON, Barnsley (37, Class XIV., p. 512), for a variety of fabrics of excellent quality, distinguished both for design and economy: they present a novelty peculiarly worthy of merit, being the introduction of a new material called China grass, a substance which has lately been spun by Messrs. Marshall, of Leeds. The employment of this new thread in vestings and pantaloons gives a peculiar finish to these goods.

TOLSON and SONS, Dalton, Huddersfield (116, p. 490), for an excellent assortment of vestings and other articles of superior quality, among which we particularly distinguish some Scotch designs, with silk and wool, brilliant and cheap. There is also a lady's cloth, lightly dressed, of particular merit. Their fabrics generally are of high merit. Medal awarded in Class XII.

WALMSLEY, H., Failsworth, near Manchester (51, Class XI., p. 482), for poplins of a new and cheap description, with several other fabrics of excellent character, showing great ingenuity.

WEIGLE, J. J., Ludwigsburg (29, Wurtemberg, p. 1115), for a fabric of vestings of cotton, carded wool, plain, and crossed with silk, an excellent description of valuable well manufactured. Medal awarded in Class XI.

The Jury make Honourable Mention of the following Exhibitors:—

AKED, T., and SONS, Halifax (137, p. 491), for pantaloons cloths of cotton and goats' hair, and light coatings, very well manufactured, and of very good colours.

BACHOVEN and VOLLSCHWITZ, Zerbst (830, Prussia, p. 1095), for silk and cotton plush, highly esteemed for the linings of caskets. (Awarded in Class XIII.)

BARBOZA, J. (683, Portugal, p. 1315), for excellent fabrics for pantaloons, of good manufacture, strong, and giving great promise of equality with the productions of other countries.

BENNETT and Co., Abingdon Street, Manchester (185, p. 495), for specimens of Utrecht velvet. One design in relief, made in the Jacquard loom, is well worthy of notice; more, however, for the happy idea than for the excellence of its execution. Credit is due to them for the introduction of the article.

BONTE, L., Roubaix (33, France, p. 1172), for pantaloons stuffs of cotton warp, shot with wool, of well-chosen colours and good materials, at prices suited to the working classes.

BULL and WILSON, London and Bradford (12, p. 486), for wristcoatings of wool called buckskins, being a kerseymer of very fine texture, embroidered with silk by children of twelve years of age. The work is of remarkable beauty, particularly in its character.

BURKHARDT, H. T., Crimmitschau (109, Saxony, p. 1109), for light cloths, cassinets, the qualities and colours of which are good.

COCU, A., 58 Faubourg du Temple, Paris (125, France, p. 1177), for vestings of cashmere design, of good quality, and well-assorted colours for general consumption.

DAUPLAZ and Co. (853, Portugal, p. 1315), for most creditable goods of various kinds. We noticed waistcoatings in the Scotch style, made of wool, cotton, and silk. (Honourable Mention awarded in Class XIX.)

FRY, W., and Co., Dublin (267, p. 499), for furniture pieces, manufactured in a superior manner; also for some fair specimens of dress pieces plain and figured.

GILSON and BOSSUT, Tournay (241, Belgium, p. 1158), for specimens of pantaloons stuffs of linen warp, strong, useful, and cheap.

HESS, G., 6 Rue de la Villière, Paris (263, France, p. 1189), for vestings of considerable excellence of manufacture.

LEHMANN, D. J., Berlin (136, Prussia, p. 1055), for specimens of plush and woollen velvets, plain and printed. We also noticed some in two colours made on the Jacquard, after French designs. The manufacture is good and the colours well chosen.

LEVIN, H., SONS, Berlin (114, Prussia, p. 1054), for vestings of a similar description, also worked with wool and silk on the Jacquard. Their goods are of excellent character.

MAX MEYER and Co., Berlin (133, Prussia, p. 1055), for silk and cotton plush, of excellent quality.

PFERDMENGES BROTHERS, Gladbach (574, Prussia, p. 1082), for light cloths, called cassinets, with cotton warp and carded wool weft. The manufacture is good and price moderate.

REPIQUET and SILVENT, Lyons (1432, France, p. 1244), for goods almost entirely composed of silk, and perhaps belonging to Class XIII., but we find some waistcoatings of silk velvet shot with cotton, and some poplins of good quality; the waistcoats being in particularly good taste. (Prize Medal in Class XIII.)

REYNOLDS, W., 81 Grafton-street, Dublin (266, pp. 498–99), for poplins for furniture, manufactured in a superior manner.

RUMANN and MECKEL, Elberfeld (580, Prussia, p. 1082), for vestings distinguished for their moderate cost. Cotton warp shot with silk and cotton made on the Jacquard, some of poplin and satin descriptions.

SCHOFFERD, J., Rastrick, Huddersfield (125, p. 490), for pantaloons cloths, vestings in wool, silk, and cotton, and kerseymers called "patent Britannics," all of good quality.

SCHULTE, J. H., Barmen (675, Prussia, p. 1087), for valentias and cashmere designs of good manufacture.

TRENDEL, jun. (41, Bavaria, p. 1100), for specimens of light pantalon stuffs of cotton and wool, of excellent make, good taste, and moderate price.

WILLETT, E., NEPHEW, and Co., Norwich (310, p. 501), for paramattas and bombazines of excellent quality.

### B.—SHAWLS.

#### General Remarks.

#### 1. KASHMIR SHAWLS from the East, and Imitations thereof.

From the limited nature of a Report of this kind, a complete history of the shawl manufacture will not be looked for, however interesting it might be; but such is the importance of this beautiful fabric, and of its valuable trade, that a sketch of its origin, and of its rapid European development, may well precede our particular remarks upon its present position, and upon the examples now exhibited. The source from which this article has sprung is well known to be the ancient and beautiful fabric of the Valley of Kashmir, where the excellence of the raw material stands to this day unequalled, although its manufacture has been and is still, carefully prosecuted in many parts of the world. The great beauty of the eastern tissue, considering the rudeness of the means of machinery employed as compared with those which are now available to the European manufacturer, is a marvel in the eyes of the most experienced.

The superiority of the woollen fabrics of Kashmir is to be found recorded in many ancient eastern works. In the Mahābhārath, where narrating the transactions taking place at the palace of Gunderstha, the eldest of the Pauda princes, about the period of two hundred years before Christ, it is stated\* "that the people of Kaneboja (the northern districts surrounding Kashmir) brought cloths and skins as tribute." The former were made of wool, and embroidered with gold, being, in fact, shawls and brocades.

Again, in the Ayeen Akbery,† being the institutes of the Emperor Jilaleddin Mohamed Akbur, sixth in descent from Timur (Tamerlane the Great), proclaimed emperor in 1556, we find the following interesting account of shawls:—"His Majesty has ordered four kinds of shawls to be made: 1st. Toos affee (grey affee), which is the wool of an animal of this name whose natural colour, in general, is grey, inclining to red, though some are perfectly white; and these shawls are incomparable for lightness, warmth, and softness. Formerly they were made of the wool in its natural state, but his Majesty has had some of them dyed, and it is surprising that they will not take a red colour. 2nd. Sufed alech (white alech), which they also call terehdar. The natural colours of the wool are white or black, and they weave three sorts, white, black, and grey. Formerly, there were not above three or four different colours for shawls, but His Majesty has made them of various hues. 3rd. Zerdozy and others,‡ which are of His Majesty's inventions. 4th. From being short pieces, he had them made long enough for jamels (gown-pieces). The shawls are classed according to the day, month, year, price, colour, and weight; and this manner of classing is called missel. The mushrif, after examination, mark the quality of each upon paper affixed to its corner. All those brought into the palace on the day Ormuzd of the month Ferirdin (10th March) are preferred to those received afterwards, of the same fineness, weight, and colour, and each is written down in order. Every day there are received into store the following kinds,§ and from this account of

one day may be formed an idea of what is done in the course of a year.

"Formerly, shawls were but rarely brought from Kashmir, and those who had them used to wear them over the shoulder in four folds (*vide* ancient sculptures), so that they lasted for a long time. His Majesty has introduced the custom of wearing two shawls, one under the other, which is a considerable addition to their beauty. By the attention of His Majesty the manufacture in Kashmir is in a very flourishing state, and in Lahore there are upwards of a thousand manufactories of this commodity. They also make an imitation of shawl with the warp of silk and the woof of wool, and this kind is called *mayan*. Of both kinds are made turbans, &c."

With this account before us, it is reasonable to suppose that varieties of every kind were introduced about this period; and the evident encouragement given to these improvements doubtless tended much to the progress of this trade, while these shawls continued to be a favourite article of dress, during the Mahomedan dynasties in particular. After their decline, it is probable that the troubled state of Upper India, and the general turbulence of the mountain character, had its effect in retarding the progress of a trade involving the labour of so many hands; but its absolute necessity as an article of wearing apparel to every well-dressed native of India, Persia, and parts of Turkey, effectually prevented the manufacture from falling into decay, even at the worst of times. It was once said that there were upwards of 30,000 looms at work; but Strachey, who visited the country in 1809, gives 16,000 as the number at that time. The value of the whole produce was estimated at 35 lacs of rupees, but Moorcroft, who was there in 1822-23, says it had declined to half that sum. A renewed vigour has been instilled into it within the last thirty years by the constantly increasing demands of the European markets; and the present improved state of government, of social rights and intercourse, in that part of India, will of course add greatly to the energies of a persevering and pains-taking people, and will most probably give early proof that its resources have never been fully developed. The valley itself is now in the hands of Goolab Singh, a chief who fully appreciates the value of the trade; but many of his measures are oppressive to the manufacturer, and some of the best makers are finding it to their advantage to settle in the neighbouring cities, under the British Government, where they are able in perfect freedom to push their trade to any extent. Unritzer and Lahore are already showing rapid progress in this trade, and there is no reason why their productions should not equal in all respects those of Kashmir; while the demand for Europe is actively promoted by European agents residing there, for the express purpose of encouraging perfection in design, colour, and texture. The activity of the present trade may be estimated from the following returns, procured from the firm of Ripley and Brown, the leading brokers in this trade:—

|         | Imports. | Deliveries. | Exports. |
|---------|----------|-------------|----------|
| In 1842 | 2,484    | 2,740       | 2,218    |
| 1843    | 2,726    | 2,992       | 2,298    |
| 1844    | 4,957    | 4,127       | 2,757    |
| 1845    | 7,981    | 5,411       | 3,860    |
| 1846    | 3,709    | 5,429       | 3,400    |
| 1847    | 3,989    | 4,354       | 3,045    |
| 1848*   | 2,389    | 1,904       | 1,484    |
| 1849*   | 1,183    | 3,311       | 2,403    |
| 1850    | 6,982    | 5,753       | 4,242    |
| 1851†   | 4,034    | 2,898       | 2,139    |

We find publications in France, "sur la fabrication des châles," which give the date of about 1800 as the period

pine-shaped; aby, watered; zytoon, olive-coloured; segevy, liver-coloured; zemroody, emerald; benefsa, violet; fakhitchy, ring-dove colour.

\* Troubles in Europe and in India.

† Up to May.

\* *Vide* vol. II., p. 140.

† *Vide* vol. I., p. 105.

‡ Zerdozee, gold-leaved; goolabun, rose body; kosheedeh, worked; kulgha, pine-shaped; Bandhemim, spotted; cheet, like chintz; alech (ignor.); perzdar, with a nap.

§ Toos, grey; sefed, white; lazereen, red-golden; narenjee, orange; berenjy, rice-coloured; kabzy, straw-coloured; gulpumbeh, rose-cotton; sendely, sandal-wood; badamee, almond; arguwanee, bright red; anaby, musk-perfumed; assely, pure; gulkaanee, cockcomb-colour; sibeky, light; alfee, marked with alifs or sprigs; festoky, sea-green; pezhgul, a Turkish wood; goolkhear, spotted; nezylbeecr, spearhead; asmany, sky-colour; goolabee, rose; kulghy,

of the first introduction into France of the taste for this article of dress, and of their first importation from Egypt, where undoubtedly they had found their way from the eastern emporium, chiefly through Persia. In England, however, the fashion had been earlier introduced by those connected with the East India Company's trade, and they were included in the periodical sales of prohibited goods, held at the East India House as early as 1750. In 1787, we find they were admitted by our Custom-house, upon payment of an *ad valorem* duty of 27½ per cent., which duty has since been thus changed, by various acts and regulations:—

|      |   |   |   |     |   |              |
|------|---|---|---|-----|---|--------------|
| 1812 | - | - | - | £81 | 2 | 11 per cent. |
| 1813 | - | - | - | 62½ |   | "            |
| 1814 | - | - | - | 67½ |   | "            |
| 1825 | - | - | - | 30  |   | "            |
| 1842 | - | - | - | 7½  |   | "            |
| 1846 | - | - | - | 5   |   | "            |

The severe restrictions upon their importation, and their consequent costliness, induced the weavers of Norwich to make the first attempt at imitation of the Indian fabric; and we are informed that in 1784 Mr. Barrow and Alderman Watson, of that town, succeeded in weaving the first Indian style of shawl we believe ever made in Europe. The process was too slow and unprofitable to induce them to continue their operations; but Mr. John Harvey, of the same town, followed up the enterprise with Piedmont silk warp and fine worsted shoot, the designs being worked in by a process of darning by the hand. No great progress, however, appears to have been made in this tedious and expensive process, and not till 1805 was an entire shawl produced from the loom in Norwich. In Paisley and in Edinburgh they took up the manufacture about the same time, but the former town has alone retained it, making India imitations now of real Kashmir wool thread, at very low prices, to a large extent.

In 1802 a commencement was made in Paris; and it is related, that the enormous expense of 60,000 francs, expended in setting the loom prepared for the purpose, induced the immortal Jacquard to invent his wonderful process of working intricate designs with facility. In 1819 great success had been reached upon looms à la Ture, with Kashmir wool imported for the purpose, and spun with great skill in France. Not earlier, however, than 1834 was the present process, called *spooling*, which is the exact imitation of the Kashmirian, so introduced for working intricate designs that one man, with a Jacquard loom, can produce the excellence now attained in Paris. In fact, we find the true Indian shawl there produced, but perfected by the addition of machinery, and sold at about a quarter of the cost in India, their range of prices being, for squares of full size, 25 to 600 francs, and for long shawls of full size 50 to 1500 francs: 4,000,000 francs is given as about the value of the total production of these fabrics in France at the present time; that of Scotland cannot so easily be estimated, but it is very large, though the shawls are chiefly of a cheaper description, ranging from 7s. 6d. to 5l. per square, and 1l. to 15l. for long shawls. We have dwelt thus at length upon the productions of France and England because of the greater development of the manufactures in these countries, where it had been first introduced; but we find that within the last five years Austria, the States of the Zollverein, and Belgium have been setting their looms upon similar produce; and with such excellent material at command, and such ingenious and industrious artisans, they may soon vie, in cheapness at any rate, with either of their predecessors in the trade. There is a peculiarity in the character of a real Kashmir shawl, as well in originality of design as in solidity and durability, which, notwithstanding the enormous difference of cost, will retain its value in the eyes of those who can afford to pay it. The finer descriptions cannot be purchased in the valley under 300 to 1,500 rupees for square, and 450 to 2,000 rupees for long.

#### Particular Remarks.

We find the following number of contributors of the descriptions called "woven," "printed," "embroidered," and "tartans":—

|                   | Woven. | Printed. | Embroidered. | Tartans. |
|-------------------|--------|----------|--------------|----------|
| France            | 15     | 7        | 4            | 6        |
| Algiers           | 1      | -        | -            | -        |
| Belgium           | -      | 1        | -            | 1        |
| Austria           | 10     | 1        | 3            | 5        |
| Hamburg           | -      | 1        | -            | -        |
| Zollverein        | 7      | 2        | -            | 2        |
| Russia            | 1      | 3        | -            | -        |

| Van Diemen's Land | -      | -        | -            | 1        |

Among whom we proceed to notice those who are most worthy of remark.

#### 1. WOVEN SHAWLS.

THE HONOURABLE THE EAST INDIA COMPANY has contributed to this Exhibition such a costly and gorgeous display of the very best specimens of every description of manufactures within their dominions, each in its kind so choice and perfect, and of a taste so original, as to afford example to all Europe, that as exhibitors of the most distinguished character we cannot but recommend that their display should be suitably recognised by Her Majesty's Commissioners.

There are many articles which do not strictly come under the cognizance of our Class, but it has been considered preferable to combine as much as possible the Report upon this collection of fabrics, rather than scatter the notices upon each different substance among many Classes.

We proceed to notice particularly,—

From Kashmir, a square shawl of perfect design and tissue; two long, fine white ones, of beautiful texture, and others (p. 915), presented by MAHARAJAH GOLAN SINGH; some pieces of superior shawl cloths, called *kid cloth*, and *Purrepuz*; this is looped in the web at the back.

From Indore, shawls and embroideries, and other articles, by MAHARAJAH RAO SCINDEAH (pp. 915 and 916).

From Puttealla, shawls, scarfs, and rich tissues, by the RAJAH OF PUTTEALLA.

From Loodiana, shawls for cheapness of price.

From Benares, splendid brocaded shawls and scarfs, from RABOOQDEO NARAYN.

From Ahmedabad, the same description of goods.

From Moorshedabad, the same, with some gold prints.

From Indore, the same.

From Madras and Bengal, beautiful embroidered muslin scarfs and shawls, of remarkable texture and elegant taste.

From Bengal, a very curious white muslin shawl-scarf, worked with gold, in which the turning of the shuttle shows extraordinary skill.

From Dacca, two shawls, embroidered with gold and silver needlework; executed for Her Majesty. Some elegant scarfs, embroidered with coloured silks of Sherry; oriental taste.

From Delhi, some splendid specimens of needlework.

From Ahmedabad, a curious specimen of cloth of gold, worked by hand; exhibited by Mr. CHARLES COPLAND.

From Kashmir, a splendid shawl, worked in many colours with gold and silver; exhibited by the PENINSULAR AND ORIENTAL STEAM COMPANY. A very handsome long shawl, called an *Alvandar*; exhibited by Mr. JOHN GRAHAM.

It would be endless to point out all the excellencies which this portion of the Exhibition puts forth. The entire Catalogue of the Indian-department may be well called the correct list of them, for all of them are worthy of notice, and will, no doubt, afford to manufacturers of all nations a means of finding that they have still something to learn.

CLABURN and SON, Norwich (284, Classes XII. and XV., p. 500), are exhibitors of the very first-class shawls of a similar style and perfection. They also present poplins, paramattas, and a variety of beautiful fabrics of the highest order. The fabrics of this firm are remarkable for their perfection of manufacture, and good taste in design, for their variety and novelty, and for all those qualities which characterize first-rate manufacturers; but a member of the firm being upon this Jury, their productions are not under our review for particular distinction.

GAUSSEN and Co., 1 Rue de la Banque, Paris (1242, France, p. 1237), have furnished a selection of very beautiful shawls of Indian wool, got up in the most perfect and classic style. Their manufacture is of the highest class; but the leading member of the firm being upon our Jury, they are out of the pale of competition.

MORGAN, JOHN, and Co., Paisley, Scotland (299, Classes XII. and XV., p. 500), have contributed a fine collection of shawls of the highest character for design and manufacture. They are dyers of their own yarn, and dressers of their own produce, and are in all respects manufacturers of the very first repute; but the senior member being upon this Jury, their goods are not under consideration for any Prize distinction.

WEINER and HAIRS, London (277, Classes XII. and XV., p. 499), have exhibited a great variety of printed shawls of excellent taste. Mr. Hairs being, however, an Associate Juror, their goods do not come under Prize consideration.

#### *Council Medal.*

DENEIROUSE, E., BOISGLAVY, and Co., 16, Rue des Fossés Montmartre, Paris (1182, France, p. 1234), for a long white shawl, made precisely upon the same principle as those of Kashmir, and distinguished by the character of "spouliné." This shawl is of peculiarly fine texture and design, combining natural flowers, in all their various tints, with the style peculiar to India: it is perfect in all respects. There is also a long white, of a new and original design; it is remarkable for the introduction of a new process, adapted to the Jacquard loom, by which, with the usual colours, a great variety of tints may be made by combinations of different threads in the web. This is a new and important discovery, which, added to the excellence of their manufacture, in all respects entitles these exhibitors to the recommendation of the COUNCIL MEDAL, and this award was confirmed.

The Jury award Prize Medals to the following Exhibitors:—

BERGER, JOSEPH, and SON, Vienna (309, Austria, p. 1022), for a highly creditable collection of shawls of elaborate style, a long one in particular with various-coloured compartments, and a square of Kashmir wool worked with gold, are deserving of great merit for good taste and colouring; others of entire wool are highly creditable for their moderate cost.

BLAKELY, E. T., Norwich (285, Classes XII. and XV., p. 500), for a square shawl of purple ground with many compartments, of various colours, in which gold is introduced, perfect of this particular school. The Barège scarfs are of superior quality and novel taste. His goods are of the highest merit.

BLISS, WILLIAM, Chipping-Norton, Oxfordshire (270, Classes XII. and XV., p. 499), for a variety of shawls, made from different materials, and of great merit for the adaptation of new articles for tissue, such especially as the vicuña, which is here shown to great advantage: she is an enterprising manufacturer of great merit.

BOAS, BROTHERS, Paris (68, France, p. 1174), for shawls of a very particular style, and of extraordinary composition; we notice in particular a long white of curious design and colouring, which possesses much ori-

ginality, and is well manufactured. Their shawls are of Indian wool yarn, and deserving of a high degree of credit.

DAMIRON and Co., 6 Rue des Capucins, Lyons (1167, France, p. 1233), for a collection of fine wool shawls of good style and make, and at very moderate prices.

DUCHÉ and Co., 1 Rue St. Petits Pères, Paris (1592, France, p. 1263), for great general excellence. This firm manufactures the largest quantity of fine shawls in France, and has exhibited the greatest variety of rich specimens in this Exhibition. They are of superior make and design. We particularly call attention to a long white shawl, of extraordinary manipulation, manufactured entirely of Indian wool yarn, and the finest ever made, having 320 shoots to the inch. Another long white, of new and original aspect: the inner border is formed by double grounds, shaded of different tints, graduating from the darkest to the lightest; the colours, being clear and distinct, show the design in all its perfection. Gold and silver threads are used both in warp and weft, to increase the number and brilliancy of the tints. There is also a square, with different compartments of various colours and ground, of very perfect design. We considered that the Council Medal should be awarded to this Exhibitor; but this recommendation was not confirmed by the Council of Chairmen. The productions of this house are of the very highest order of perfection, combining excellence in material, manufacture, colour, and design, with much originality.

FORBES and HUTCHISON, Paisley (291, Classes XII. and XV., p. 500), for cheapness of manufacture and general excellence.

GAUSSEN, FARGETON, and Co., 2 Place des Victoires, Paris (1243, France, p. 1237), for a variety of shawls of India wool, with very elaborate effects, and of superior manufacture. We notice particularly a long white on two grounds, in which there is excellent harmony in colouring and design; again a square white of very rich style and careful manipulation. In all there is great merit.

GRILLET and Co., 11 Place Croix-Paquet, Lyons (1259, France, p. 1237), for two long shawls of very elaborate design and excellent manufacture. The striped pattern is worthy of particular notice for novelty and harmony: their known superiority of manipulation gives rise to regret that they have not exhibited a greater variety.

HÉBERT, F., and SON, 13 Rue du Mail, Paris (1621, France, p. 1255), for shawls woven from Indian wool yarn of the very first class, being a classic and harmonious imitation of the Indian style. There is a long one with ground of four colours, very successful in its colouring; a square amber colour is very true to its Indian origin; and altogether this firm is decidedly worthy of merit for its careful products.

KERR, ROBERT, Paisley, Scotland, and of the firm of Kerr and Scott, London (300, Classes XII. and XV., p. 500), for remarkably fine specimens of every description of shawl, in all textures, all of which are stamped with the character of superiority, and the highest degree of skill in manufacture. We considered his goods to be pre-eminent in design, novelty, variety, and texture, and accordingly recommended him for the Council Medal, which the Council of Chairmen did not, however, grant.

LION BROTHERS, and Co., 9 Place des Petits Pères, Paris (1827, France, p. 1239), for a handsome collection of shawls, of elaborate design and excellent make; a long white is well worthy of notice. There are two squares of peculiar style, in which the white and yellow effects are produced by gold and silver thread. Their manufacture is of distinguished merit.

MERLIN, A. and V., Government of Riasan (281, Russia, p. 1375), for a long white shawl made of fine wool, conspicuous for its beautiful texture, and for a handsome border of modern floral design, quite original, which presents the same effect on each side of the shawl, the centre being sewed in according to the Indian manner. It is a novel and extraordinary production of high merit, and though scarcely to be considered an object of trade, it may lead to one of importance hereafter.

ROBERTSON, J. and J., Paisley (301, Classes XII. and

XV., p. 500), for cheapness of manufacture and general excellence.

**TOWLER, CAMPIN, and Co.,** Norwich (309, Classes XII. and XV., p. 501), for a very choice collection of long shawls, of different compositions of spun silk and wool. They are of elaborate and original designs, showing superior skill in workmanship, and the highest degree of merit a manufacturer can attain. Every improvement is here adopted without abandoning the distinguished character of the original Norwich style. We find also printed shawls on a grenadine gauze of great merit, and a square with silk worked on cashmere ground, very beautiful. All their productions show great perfection in a school peculiar to this town, and always to be admired, and they are of the highest degree of merit. We therefore recommended a Council Medal to these exhibitors; but it was not conceded by the Council of Chairmen.

**ZEISEL, J. and J., and C. BLÜMEL,** Vienna (320, Austria, p. 1022), for a collection of shawls, among which a long white of woollen warp, and another with four compartments of elaborate French designs in good taste, made of Cashmere wool, are worthy of particular remark for excellence of manufacture. Others of more moderate cost are also deserving of great merit, showing much perfection in the working of their woollen thread.

The Jury make Honourable Mention of the following Exhibitors:—

**BONFILS, SOUVRAZ, and Co.,** 3 Rue des Fossés Montmartre, Paris (1094, France, p. 1230), for specimens of shawls of excellent design and manufacture; we point in particular to a long one with pink ground and orange compartments: a very successful combination, and possessing much novelty.

**CHAMBELLAN, G., and Co.,** 8 Rue des Fossés Montmartre, Paris (1140, France, p. 1232), for a collection of shawls of superior manufacture from Indian wool yarn; in particular a long one of excellent design, and a square in four compartments, are well worthy of notice.

**CHENARD, CHARLES,** 9 Rue de Cléry, Paris (89, France, p. 1175), for a collection of shawls of very good make and careful combination of colours; particularly a new style of square adapted for summer fashion, differing from the ordinary method of weaving.

**HALEY, JOHN, and SON** (58, Classes XII. and XV., p. 488), for some peculiarly soft flannel shawls, made of goats' hair, the produce of stock reared by H.R.H. Prince Albert in Windsor Park.

**HAYDTER, SEBASTIAN,** Vienna (311, Austria, p. 1022), for moderate-priced goods, and very creditable specimens of long shawls of good effect, at from 40s. to 45s., and a black square at 24s., which are decidedly cheap.

**MARX and WEIGERT,** Berlin (113, Prussia, p. 1054), for a collection of long and square shawls on spun silk warp, with wool and mixture weft; of good design and very effective, and of moderate prices.

**OPDENHOFF and HARTUNG,** Berlin (134, Prussia, p. 1055), for several harness shawls, as well as tartans, of good taste and manufacture; their colours are few but effective, and prices very moderate.

**PIR-BAYARD,** Roubaix (682, France, p. 1211), for a collection of damask worsted shawls, of peculiarly soft texture and excellent make: when their moderate cost is considered we cannot but give him much credit. (Prize Medal awarded in Class XII.)

**REINHOLD, W.,** Vienna (315, Austria, p. 1022), for a variety of long and square shawls of very good taste in colour and design, and for effective goods at a low price.

**RISS, JOSEPH,** Vienna (316, Austria, p. 1022), for shawls of a low quality, presenting them solely for merit as to cheapness.

**ROXBURGH, JOHN and ANDREW,** Paisley (296, Classes XII. and XV., p. 500), for specimens of woven shawls, of good designs; also shawls made on spun silk warp, in which an ingenious advantage is taken of short reeding in design, which reduces the expense of production.

**SABIN, REMOND,** Lyons, for a good assortment of cravats, scarfs, square and long shawls, of good colouring and design, chiefly suited to a large consumption at low prices.

## 2. SHAWLS OF BARÈGE, CRAPE, GAUZE, SILK, AND OTHER DESCRIPTIONS.

### General Remarks.

The rapid progress in the manufacture of shawls, and the increasing taste and demand for this style of garment, has led to the introduction of many kinds of lighter fabrics, in either wool, silk, goats' hair, or the various combinations of these with other materials, such as cotton, spun silk, &c.

These descriptions are generally traded in under the following denominations:—

**Crapes,** made of silk, in imitation of Chinese fabrics; chiefly manufactured at Norwich and Lyons.

**Barège,** made of wool, an improved imitation of shawls made in the Pyrenees, by the peasantry of a place so named; remarkable for their lightness, elasticity, and strength.

Another sort, with silk warp, and with a check of silk; a new introduction for increasing the effect of printing.

**Grenadines,** made of silk of a peculiar twist, which gives hardness and durability, but at the expense of brightness.

**Levantines and Albanians,** made of silk and spun silk, in imitation of the scarfs from various parts of the Mediterranean.

**Chenille,** a novel application of silk, sometimes with cotton.

**Chiné,** a printed warp before weaving.

The trade in these articles has already in a few years become most important, giving employment to an immense number of artisans in various branches besides those of spinning and weaving, such as designers, carvers, chemical colourists, and dyers.

In the perfection of these goods, France has taken the lead, and to her early encouragement of schools of design, and well-known national taste, may be attributed the tone and fashion she has given to all Europe; but her work is more expensive than that of England, and large quantities of these goods are brought over to be printed here at the lower cost, which the greater division of labour and the more extended development of the trade has accomplished.

In these printed articles, Austria shows evidences of an active endeavour to produce imitations of the designs of France.

In the exhibition by the States of the Zollverein we also perceive the foundation of a future trade in these fabrics.

### Particular Remarks.

The Jury award Prize Medals to the following Exhibitors in this department:—

**CHOCQUEL, FELIX,** Paris (1148, France, p. 1233), for great excellence in the printing of light shawls. For a long time foreman to his brother, he has acquired much of his perfection. We point especially to a long white shawl of elaborate design, the cutting and printing of which prove him to be a manufacturer of great merit.

**CHOCQUEL, LOUIS,** Labricht, near St. Denis (90, France, p. 1175), for a collection of printed shawls, on barège, cachemire d'écosse, and other fancy goods, of great excellence in design, harmony of colours, and perfection of printing, which is conspicuous in the great clearness of his white grounds, the whole being of the very highest merit. Medal awarded in Class XVIII.

**GLEN and McINDOE,** Glasgow (279, Classes XII. and XV., p. 499), for the economical execution of the printed shawls exhibited by Messrs. Keith, Shoorbridge, and Co.

**KEITH, SHOORBRIDGE, and Co.,** 124, Wood Street, London (279, Classes XII. and XV., p. 499), for a large collection of printed shawls, scarfs, and mufflers, of excellent design and execution. They are deserving of merit for the goods they have made up on their own designs. But to Glen and McIndoe, Glasgow, their printers, we consider much credit to be due, for the execution of the detail, which for colour and neatness is very remarkable.

**SWAISLAND, C.,** Crayford, Kent (283, Classes XII. and XV., p. 500), for goods that prove him to be a printer of the very first class. We point especially to an elaborate

rate design on a barège ground, which has required 550 blocks to complete the pattern. The colouring is bright and clear; the execution perfect. At his extensive works the art of printing on wool has been carried to great excellence.

**THIRRY-MIEG**, Mulhouse (1506, France, p. 1248), for a large collection of shawls, square and long. The designs are of classic style, clearly and neatly executed, and the sharpness of outline well preserved. The goods are cheap, and of decided merit.

**TOWLER, CAMPIN, and Co.** (286, p. 500), and **E. T. BLAKELY**, Norwich (285, p. 500), are both manufacturers and exhibitors of first-class printed goods, but have received their awards of merit under the head of woven shawls.

The Jury make Honourable Mention of the following Exhibitors:—

**DEPOUILLY BROTHERS, BOIVAUX, and Co.**, Paris (1586, France, p. 1252), for a good selection of barège shawls, printed with taste and accuracy. The colours and composition do much credit to M. Boivaux, the designer.

**GODEFROY, LEON, Purteaux** (1252, France, p. 1237), for a few specimens of shawls printed on fancy barège, with dark grounds of great perfection in clearness and precision. He is a printer of the first class; but having a larger collection of dresses than of shawls, he will be more particularly noticed elsewhere.

**JAMESON and BANKS**, Honey-lane Market, Cheapside, London (278, Classes XII. and XV., p. 499), for a large collection of superior shawls on various grounds, some with novel floral designs, executed in the most perfect manner, and printed by the first men in the art; such as Swaisland, Littler, and David Evans and Co.

**LAWSON, J., and Co.**, Caledonia Print Works, Paisley (294, Classes XII. and XV., p. 500), for excellent specimens of printing, of good effective and clear designs, which are moderate in price.

**LEWIS and ALLENDY**, Regent Street, London (276, Classes XII. and XV., p. 499), for a design of their own composition of peculiar Indian style, very classic and effective; printed on several grounds by Swaisland in a superior manner.

**LITTLER, MARY ANN**, Merton Abbey, Surrey (282, Classes XII. and XV., p. 500), for shawls of Indian style, designed and executed by herself, showing great excellence in the art of printing. Medal awarded in Class XVIII.

### 3. SHAWLS, EMBROIDERED WITH WOOL, SILK, THREAD, GOLD, SILVER, &c.

#### General Remarks.

There is no doubt of the origin of this description of manufacture being traceable to eastern nations, where, in truth, we still find the most perfect workmanship and the greatest variety of design, with perfection of colouring. There, unquestionably, all uses of the embroidery-needle have been learned. The web of Penelope was no new thing in her time to the nations farther east. The Israelites were enjoined to have the door of the tent of their first tabernacle a "hanging of blue and purple, and scarlet and fine twined linen, wrought with needlework."\* Deborah, in her song of triumph, 1296 years B.C., sings of the "prey of divers colours of needlework, of divers colours of needlework on both sides."† No better evidence can be needed of the antiquity of embroidery.

We have from China some specimens of the most exquisite work of this kind, unsurpassed by that of any other nation. We regret that nothing has been sent from Japan, where it is understood that embroidery is carried to great perfection. It is most probably from Tartary that Russia has derived her excellence: the specimens produced on this occasion not being shawls, will, we trust, be noticed in their proper Class. India stands pre-eminent in the exhibition of embroidered shawls, whether in coloured wool or silk, upon Kashmir, cloths, or in gold and silver brocades; in short, in almost every variety of form or description.

\* Exodus, chap. xxvi., v. 36. † Judges, chap. v., v. 30.

Persia is not fairly represented on this occasion, for she has artisans of the highest merit; witness the beauty of her carpets, a species of embroidery in the manner of their manipulation; and she could have sent some excellent shawls, scarfs, and roomals.

Turkey has given a very handsome display of the excellence of her manufactures, and of the richness of her taste in embroidery of every kind; but her shawls do not evince equal talent or originality, being mostly copies of Indian designs.

Greece exhibits only some gauze scarfs, worked with tinsel. She does not appear to maintain the character she formerly held for this kind of work.

Egypt shows no originality in this fabric; her silk and gold scarfs are not of a fine character, and are of the same description as those of Turkey.

In Paris, Paisley, and Vienna the embroidery, of shawls and scarfs on various materials is carried to great perfection; but the demand for such goods is not very great, the process being naturally expensive.

#### Particular Remarks.

**Turkey.**—The Government of Constantinople have placed on view a valuable collection of embroidered scarfs and roomals (handkerchiefs), of superior taste and fabrication, fully maintaining the renown of Levantine manufactures. The shawls are scarcely equal in character for excellence. There are some kumcabs, made at Damascus, worthy of remark; also some Albanian scarfs, of cotton cloth mixed with silk and tinsel, made at the Imperial factory; not without merit, considering the difficulties attending the introduction of machinery into that country. Altogether, the collection is a valuable exhibition of the progress of manufactures in Turkey, and worthy of the most Honourable Mention.

**India.**—The East India Company's collection has already had special notice. We however point particularly to the gorgeously-brocaded square shawls, and the long red shawls embroidered with gold and pearls; to the muslin scarfs embroidered with gold thread and beetles' wings. It would be tedious to mention the various excellencies, as all are of the very highest order of merit.

The Jury award Prize Medals to the following Exhibitors:—

**FOULQUIÉ and Co.**, Paris (1603, France, p. 1253), for net shawls embroidered with silk, rich, elegant in design, of novel character, well executed, and quite worthy of the Prize Medal. (Medal awarded in Class XIX.)

**GRAHAM, JOHN**, Ludgate Street, London, embroidered crape shawls of peculiar excellence in texture, colour, and design. They are probably the finest specimens ever brought from China, and of the highest possible merit. We hold the Exhibitor to be worthy of the Prize Medal as the importer.

**LAPORTA, H. F.**, Vienna (387, Austria, p. 1029), for embroideries on several textures, most of which show great skill in that art, and a perfect adaptation of material to colour and design.

**WHITEHILL, M., and Co.**, Paisley (287, Classes XII. and XV., p. 500), for superior merino shawls embroidered with silk, of which the taste and execution are conspicuous, proving them to be manufacturers of high merit.

The Jury make Honourable Mention of the following Exhibitors:—

**HENRY, LEENESE, and Sons**, Glasgow (13, Class XI., p. 480), for a good selection of embroidered merinos, of good taste and execution.

**MAIR, JOHN, Son, and Co.**, Glasgow (59, Class XI., p. 482), for a good selection of embroidered merinos of good taste and execution. (Medal awarded in Class XIX.)

**STREIBER, FREDERICK**, Vienna (271, Austria, p. 1030), for well-executed embroideries.

### 4. TARTAN PLAIDS, SHAWLS, SCARFS.

#### General Remarks.

This peculiar manufacture is of very ancient date, and many learned researches have been made to endeavour to

trace its introduction into the British isles, and into Scotland in particular, where it has so long remained the well-known national costume, giving a name to its peculiar style that is universally adopted in every part of the world where the manufacture is produced or traded in. Great difficulty has been found in the derivation of the word Tartan: it does not appear in Gaelic, nor was it used in the Highlands, where the word Breachan was its equivalent, until the sixteenth century. The ancient bards invariably used the word Breach or Breachan in Scotland, Brycan in Wales, and Breacan in Ireland, where the dress prevailed from very early times. A woollen fabric of this description appears to be clearly traced from the northern tribes of Europe, very far east. In Russia, and among the Calmucks, it is common to this day; in Burnah, the chequered design, although mostly in silk, is the common dress of the country. There are strong evidences of its having been of Scythian wear; it may be fanciful to trace Tartan to Tartaric origin, but it is curious to find the Arabic word *Berkas* meaning "party-coloured." Livy describes the party-coloured woollen cloths of the Gauls, Germans, and Goths. Pliny, again, states that the dress of the Gauls was woven in squares of party-coloured fine wool. Dio, writing in the third century, describes the Britons in cloths of divers colours, which were called by their bards "Breach," or "Breachan." There is no record of their having been the distinctive dress of the clans of Scotland before the sixteenth century; but in a chartulary of Aberdeen, in 1269, the canons of the Church forbid the clergy to wear the party-coloured garments under the name of *Tyretains*. This word was brought into use from Normandy in the eleventh century, and may very probably be the origin of the word Tartan, for it is frequently used in reference to these woollen cloths of many colours. In the fifteenth century the records of the Royal Wardrobe give an item of expenditure, describing the colours of these Tyretaines. In 1570 an ancient Scottish manuscript gives a list of the colours of the plaids of the different clans. In 1747 the wearing of this distinctive dress was prohibited by Act of Parliament, and the grey shepherds' mauls were made instead. This Act was, however, repealed in 1782, but the fashion was not actively revived until very lately. The visit of George IV. to Scotland, in 1822, gave the first impulse to this revival, and in the neighbourhood of Stirling fancy plaid shawls began to be made. In 1828 clan Tartan shawls, long and square, became very popular. The Galashiels weavers took up the trade very actively, and from that period the consumption has each year been greatly on the increase. Paisley opened extensive manufactories about eight years ago, which now throw off a vast quantity. The example of that town was quickly followed by France, Belgium, many parts of Germany, Austria, and Bohemia; and in 1849 a very extensive concern was opened in Massachusetts, North America, for the production of this fabric from native wool, which has given evidence of excellence that will compare with any other country. We find also a specimen from Canada; but in this article it will probably be long before Scotland can be surpassed in design, fabric, or cheapness.

#### Particular Remarks.

MORGAN, JOHN, and Co., Paisley (299, Classes XII. and XV., p. 80), have a very handsome collection of tartans of very superior make; but, as already stated,

they are not under consideration for distinction in consequence of Mr. Morgan being a member of the Jury.

The Jury award Prize-Medals to the following Exhibitors in this department:—

CROSS, WILLIAM, 62 Queen Street, Glasgow (202, Classes XII. and XV., p. 500), for tartans of fine Indian wool, of superior make, the colours excellent, and the tissue perfect.

KERR and SCOTT, 31 and 32 St. Paul's Churchyard, London (275, Classes XII. and XV., p. 499), for a variety of tartans of the very best description, manufactured by Robert Kerr, the beauty of whose fabrics has already been fully appreciated by this Jury.

LAWRENCE, STONE, and Co., Boston, United States (464, United States, p. 1464), for a few tartans of excellent manufacture, fine in texture and bright in colours. They are made from native wool, and show much excellence as the produce of a manufactory only three years at work, but estimated to turn out this year 5,000,000 pieces. This concern, from its rising importance, is considered to be of decided merit.

LEES, R. and G., Galashiels, Scotland (192, Classes XII. and XV., p. 495), present such perfect specimens of their manufacture that we cannot but consider them as makers of the highest merit, and fully entitled to the Prize Medal.

PATON, J. and D., Tillicoultry, Scotland (466, Classes XII. and XV., p. 501), for a collection of tartans remarkable for their fineness and softness of texture, for the excellence and variety of their colours, and perfection of make.

SANDERSON, R. and A., and Co., Galashiels, Scotland (196, Classes XII. and XV., p. 495), for an excellent collection of tartans; their mauls, or shepherds' checks, are particularly worthy of notice.

VAN DER BECK, J. C., Dusseldorf (Prussia, 494, p. 1079), for a collection of fancy tartans, with ends brocaded, of peculiar style. The taste and execution are both superior; and, with reference to moderate price, this manufacture is considered to possess a decided merit.

The Jury make Honourable Mention of the following Exhibitors:—

HAAERHAUS, J. C., Sons, Elberfeld (567, Prussia, p. 1082), for a good collection of medium-priced tartans, well made and of good colours. They are extensive manufacturers.

HOLMES, WILLIAM, and BROTHERS, 7 St. Mirren's Street, Paisley (288, Classes XII. and XV., p. 500), for a complete collection of clan tartans, sixty-two in number, got up with great care, of excellent colours.

WILSON and SON, Bannockburn (468, Classes XII. and XV., p. 501), for a collection of clan tartans, fifty-eight in number, of good colours and strong manufacture. They well merit Honourable Mention.

In presenting this our Report upon Class XV., we have, in the faithful execution of our trust, unanimously decided that, among the beautiful and elaborately-made textures which have come under our examination such perfection of various kinds of merit has been found, that according to our interpretation of the instructions of the Council of Chairmen we could not do otherwise than recommend those Exhibitors who have presented a combination of such different merits as are unquestionably pre-eminent in their class, and therefore entitled to the Council Medal, which we trust will be confirmed.

WILLIAM PRINSEP, REPORTER.

London, July 1851.

## CLASS XVI.

REPORT ON LEATHER, INCLUDING SADDLERY AND HARNESS, SKINS,  
FURS, FEATHERS, AND HAIR.

[The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE.]

## Jury.

Col. the Hon. GEORGE ANSON, *Chairman*; 25 Hill Street, Berkeley Square.  
CHARLES NOTTECK, *Deputy Chairman*, Russia; attached to the Ministry of Imperial Domains.  
J. A. NICHOLAY, *Joint Reporter*, 82 Oxford Street; Furs.  
JAMES B. BEVINGTON, *Joint Reporter*, Neckinger Mills, Bermondsey; Leather Manufacturer.  
J. S. CUNNINGHAM, United States.  
JACQUES FREDERIC FAULER, France; Member of the Chamber of Commerce.  
JOHN FOSTER, 16 Wigmore Street, Cavendish Square; Florist and Feather Manufacturer.  
J. W. NEWMAN, Walsall; Saddler and Harness Manufacturer.  
HECTOR ROESSLER, Zollverein; Counsellor of Commerce.  
EDWARD ZORRAB, Turkey; Turkish Commissioner.

## Associate.

GEORGE KIDD, 257 Oxford Street; Saddler and Harness Maker.

The Jury, for convenience and certainty in examination, have distributed the articles exhibited in this Class under the following heads:—

Skins and manufactured furs.  
Feathers for ornamental purposes.  
Artificial hair.  
Woven hair for furniture.  
Rough, tanned, and sole leather.  
Curried leather.  
Varnished leather.  
Morocco and dyed sheepskin leather.  
Alum and gloving leather.  
Oil or chamois leather.  
Dyed sheepskins for rugs.  
Vellum and parchment.  
Saddlery and harness.  
Portmanteaus.

The manufacture of the skins of animals into the various useful articles to which they are applicable, has been at all times an important branch of industry, and is estimated to hold the fourth place among the manufactures of England in respect to the value of the produce and the number of persons employed.

The hides, skins, and furs upon which this labour is employed, are mostly the produce of our own country, but besides the home supply, immense quantities are imported from North and South America, Europe, and the East Indies. The estimated number imported into Great Britain annually is about 11,000,000, of which 5,000,000 are applicable for furs, and 6,000,000 are adapted for various descriptions of leather.

The following statement shows the number of unmanufactured hides and skins annually imported into Great Britain for tanning and leather dressing, a large portion of which are re-exported in the raw state:—

|                |         |           |
|----------------|---------|-----------|
| Hides and kips | - - - - | 2,550,000 |
| Calf skins     | - - - - | 270,000   |
| Horse hides    | - - - - | 228,000   |
| Seal skins     | - - - - | 593,000   |
| Goat skins     | - - - - | 484,000   |
| Sheep skins    | - - - - | 310,000   |
| Lamb skins     | - - - - | 1,430,000 |
| Kid skins      | - - - - | 48,000    |
| Deer skins     | - - - - | 90,000    |
| Total          | - - - - | 5,883,000 |

Subjoined is a table of the imports and exports of skins adapted for furs.

|                                | Total Importation into England. | Exported. | Consumed in England. |
|--------------------------------|---------------------------------|-----------|----------------------|
| Raccoon - - - -                | 525,000                         | 525,000   | None.                |
| Beaver - - - -                 | 60,000                          | 12,000    | 48,000               |
| Chinchilla - - - -             | 85,000                          | 80,000    | 56,000               |
| Bear - - - -                   | 9,500                           | 8,000     | 1,500                |
| Fisher - - - -                 | 11,000                          | 11,000    | None.                |
| Fox, Red - - - -               | 50,000                          | 50,000    | None.                |
| " Cross - - - -                | 4,500                           | 4,500     | None.                |
| " Silver - - - -               | 1,000                           | 1,000     | None.                |
| " White - - - -                | 1,500                           | 500       | 1,000                |
| " Grey - - - -                 | 20,000                          | 18,000    | 2,000                |
| Lynx - - - -                   | 55,000                          | 50,000    | 5,000                |
| Martin - - - -                 | 120,000                         | 15,000    | 105,000              |
| Mink - - - -                   | 245,000                         | 75,000    | 170,000              |
| Musquash - - - -               | 1,000,000                       | 150,000   | 850,000              |
| Otter - - - -                  | 17,500                          | 17,500    | None.                |
| Fur, Seal - - - -              | 15,000                          | 12,500    | 2,500                |
| Wolf - - - -                   | 15,000                          | 15,000    | None.                |
| Martin, Stone and Baum - - - - | 120,000                         | 8,000     | 115,000              |
| Squirrel - - - -               | 3,000,000                       | 100,000   | 2,900,000            |
| Fitch - - - -                  | 65,000                          | 28,276    | 36,815               |
| Kolinski - - - -               | 53,410                          | 200       | 53,210               |
| Ermine - - - -                 | 187,104                         | None.     | 187,104              |
| Rabbit - - - -                 | 120,000                         | None.     | 120,000              |
| Wolverine - - - -              | 1,200                           | 1,200     | None.                |
| Skunk - - - -                  | 1,200                           | 1,200     | None.                |
| Sea Otter - - - -              | 100                             | 100       | None.                |

The temperate and tropical countries supply the peculiar descriptions of hides and skins which are best adapted for leather, while the northern and arctic regions abound in races of beautiful animals which are thickly covered with fine hair or fur, whose skins are extremely valuable as articles of clothing.

To prepare the skins from the raw state, and render them fit for ornamental dress, is the first process of the fur dresser. In this country it is the usual practice to trample them in closed tubs with a little salt butter, turning them over and over for several hours; by this means the skins are made into soft and pliable leather. The next operation is to rub them on the flesh side over a blunt iron to remove loose pieces of integuments, and to reduce the substance, after which it is necessary to cleanse the fur and skin completely from the grease; for this purpose, it is again trampled with sawdust (usually from

mahogany), which being beaten out, and repeated several times, conduces to make the fur glossy and clean, and to fit it for the cutter to fashion into any shape that may be required.

The fur of most animals is in its greatest perfection at the approach of winter, and before the animal has attained its greatest age. It is the object of the furrier, by dyeing the inferior skins, to imitate the more perfect specimens. Some difficulty has attended this process, as the nature of the skin will admit of the dyes being used only in a cold state, but the method which has been practised in Paris and London has been so far successful, that the permanence of the colour in the dyed sable is frequently found of equal durability to that of skins of the natural colour. Considerable excellence has been attained also in dyeing rabbit and inferior furs of those colours which are more suitable to the prevailing taste.

The several contributions of furs in the Exhibition, taken as a whole, form a complete collection of all the skins known to be used for ornament or dress; those of the HUDSON'S BAY COMPANY, and the CENTRAL COMMITTEE OF NOVA SCOTIA, are adorned with some of the choicest skins known to commerce; but our notice would be very incomplete if we omitted to mention the remarkably beautiful and extensive collection of skins, and specimens of taxidermy, furnished to the Exhibition by several members of the nobility and other gentlemen, under the superintendence of Messrs. NICHOLAY & SON, of Oxford Street. We have also to notice the valuable articles exhibited by the same firm, on which the Jury made the following minute, 9th July, 1851:—

[The Jury having closely examined the extensive and interesting collection of furs exhibited by Messrs. Nicholay and Son, Her Majesty's furriers (301), as well as the large assortment of manufactured articles, of excellent design and workmanship, resolve;—that they consider them worthy of especial notice, and have pleasure in recording their judgment that the collection would fully entitle Messrs. Nicholay and Son to a Prize Medal, which they are precluded from awarding them, in consequence of one of the firm being a member of this Jury.]

We proceed to give a brief account of the animals that are captured for their fur, the skins of which are exhibited in various parts of the Building, commencing with—

The Russian Sable (*Mustela sibirica*).—This rich and beautiful skin has long been esteemed one of the most valuable and useful furs that have been brought to our country. About 25,000 are annually collected in the Russian territories, of which only a small number is imported into England. The fur is brown, with some grey spots on the head. The darker varieties are the most highly valued, a single skin being frequently sold for 9*l.*, though the average value does not exceed 2*l.* or 3*l.* Naturalists are not agreed whether to consider the animal from which the skin is procured as a distinct species. Some are of opinion that the Russian sable, the stone and pine martens, as well as the Hudson's Bay sable, are but one species, on which the differences of food and climate have produced some slight variations in form and colour. To the furrier, however, the Russian sable is easily distinguishable, from the length and fulness, as well as the darker colour of the fur. The use of this choice variety is necessarily limited to the wealthy, on account of its high value. In the reign of Henry VIII., by a law which sought to regulate the expenses of the different classes, and to distinguish them by peculiarity of costume, the use of the sable was confined to the nobility above the rank of viscount.

Hudson's Bay Sable (*Mustela Canadensis*).—The sable skins next in repute to the Russian are those imported by the Hudson's Bay Company, of which no less than 130,000 are annually brought into this country. As the natural colour of the skins is much lighter than the prevailing taste, it is the practice to dye many of them a darker colour, and the furs thus treated are scarcely inferior to the natural sable.

Brown or Pine Marten (*Mustela americana*).—The sables imported under this name are the produce of Europe. The animal is found in extensive forests remote from the

habitations of man, and preying on birds and the smaller animals. They are distinguished from the stone marten by the yellow colour of the throat; other parts of the skin are brown. When dyed, they have a similar appearance to the best sable.

Stone Marten (*Mustela saxorum*).—This marten is generally found in mountainous and stony places, though a frequent visitor to farm-yards and homesteads. It is generally distributed through most European countries. The under fur is a bluish white, with the top hairs a dark brown. The throat of this variety is usually of a pure white, by which character it is generally distinguished. The French manufacturers excel in dyeing this fur, from which circumstance it is frequently called French sable. It is also dyed in this country, the excellent qualities of the skin adapting it to a great variety of purposes to which furs are applied.

Fisher.—There are about 11,000 of these skins annually brought to this country from North America; they are larger than the sables, and the fur is longer and fuller. The tail is long, round, and full, gradually tapering to a point, and quite black; a few years since it formed the common ornament to a national cap worn by the Jew merchants of Poland, and at that time was worth from 6*s.* to 9*s.*, but its present value does not exceed 6*d.* to 9*d.*

Mink (*Mustela vison*).—There were 245,000 skins of this little animal brought to this country last year from the possessions of the Hudson's Bay Company and North America. The fur resembles the sable in colour, but is considerably shorter and more glossy. It is a very durable and useful fur, and is exported in large quantities to the Continent.

Ermine (*Mustela erminea*).—This animal is similar in form and habit to the common weasel of this country; but in Siberia, Russia, and Norway, from whence the skins are imported, the little animal, during winter, becomes as white as the snowy regions it inhabits, and is esteemed as the whitest fur known, though its summer dress is a dingy brown. The tail of the skin, of which the lower half is jet black, is generally introduced as an ornament to the purely white fur. It is worn on state occasions, as in the reign of Edward III., its use was restricted to the royal family.

Fitch or Polecat (*Mustela putorius*).—These skins are produced throughout Europe, and in no place of better quality than in our own country. The ground of the fur is a rich yellow, while the top hair is a jet black. This fur is at present very little used in this country, but is much worn in America. It is very durable, but the natural smell of the fur, which is rather unpleasant, is difficult to counteract.

North American Skunk (*Meophitis Americana*).—The skins known under this name are imported by the Hudson's Bay Company. The animal from which they are taken is allied to the polecat of Europe, and, from the fœtor it emits when attacked, which has been known to affect persons with sickness at 100 yards distance, has received the soubriquet of "Enfant du Diable." It has a soft black fur, with two white stripes running from the head to the tail, which is short and bushy. The skins, though imported into England in small numbers, are usually re-exported to the continent of Europe.

Kolinsky (*Mustela Siberica*).—The Kolinski or Tartar sable is of a bright yellow colour, and is sometimes used for ladies' dress in its natural state, but it is more frequently dyed brown to imitate other sable, to which it bears a strong resemblance. It is remarkable for the uniformity of its colour, having no spot or difference of shade in any part of the body. The tail, which is of the same colour, is exclusively used for the best artists' pencils.

Musquash, or Musk Rat (*Fiber sibiricus*).—The animal known under this name is found in great numbers in North America, frequenting swamps and rivers, and, like the beaver, building its habitations of mud with great ingenuity. Dr. Richardson states, that it has three litters of young in the course of the summer, producing from three to seven at a litter. The animal has a peculiar smell, similar to that of musk; but it must not be mis-

taken for the animal from which the musk of commerce is procured, which is a native of Tibet. About one million skins are brought to this country annually; the fur resembles that of the beaver, and is used by hat manufacturers. The skins are also dyed by the farrier, and manufactured into many cheap and useful articles.

**Nutria, or Coypou** (*Myopotamus coypus*).—This rodent quadruped is an expert swimmer, and frequents the neighbourhood of water, where it lives in burrows; it is smaller than the beaver, and considerably larger than the musquash, but has a resemblance to both these animals in its natural habits, and in the qualities of the fur.

Until lately this fur was very much used by hat manufacturers, and as many as 600,000 skins have been annually imported from Buenos Ayres and Chili, in which countries the animal abounds. Owing to the wars that continue to be carried on between the different states of Buenos Ayres, and the consequent withdrawal of the trappers from their accustomed occupations, the importations have fallen to 3,000 skins, which are dressed and dyed as a substitute for the costly fur seal.

**Hamster** (*Cricetus vulgaris*).—About 100,000 of the skins of the hamster are annually collected in central Germany, where the animal abounds; it has a poor, short, and coarse fur, and is almost exclusively used for cloak linings by the Greeks; the colour of the back is a reddish-brown, the belly black, with a few light spots. The animal is about 9 inches in length, and lives under ground, forming several apartments for storing grain separate from its own hybernaculum. It is so industrious and provident, that when the peasants go "hamster nesting" in the winter, they possess themselves not only of the skin but of the valuable store of good grain, which is said frequently to exceed two bushels.

**Perwitzky**.—The skin of this animal is beautifully marked like tortoiseshell, and is brought from the southern territories of Asiatic Russia; the fur is short, giving little warmth, and is chiefly made into cloak-linings, and used by the Russians.

**Beaver** (*Castor Americanus*).—Beaver skins are imported by the Hudson's Bay Company in less quantities than formerly; the use of the fur in our hat manufactures has greatly diminished since the introduction of silk hats, and a considerable depreciation has taken place in their value. This beautiful fur is sometimes used for articles of dress. In order to prepare the skin for this appropriation the coarse hairs are removed, and the surface is very evenly cut by an ingenious machine, somewhat similar to that used in dressing cloth. The fur thus prepared has a beautiful appearance, not unlike the costly South Sea otter, and has the advantage of lightness, with durability and cheapness.

The white wool from the under part of the beaver still obtains a high price, and is largely exported to France, where it is manufactured into ladies' bonnets. There is no doubt that the beaver was formerly an inhabitant of the British Isles, and Pennant remarks that two or three waters in the principality of Wales still bear the name of Llyn yr afango, or the Beaver's Lake.

**Otter** (*Lutra vulgaris*, *Lutra Canadensis*).—The large supply of otter skins used by the Russians and Chinese is derived principally from North America. The quality of the fur is in most respects similar to the otter of the British Isles, of which there are about 500 skins collected annually. This animal has frequently been tamed, and from its extreme agility in the water, has been rendered serviceable in catching fish for the use of its owner.

The American otter is much larger in size than the European, being about 5 feet from the nose to the tip of the tail; a smaller variety abounds in the East Indies, the fur of which is very short.

**Sea Otter** (*Enhydra marina*).—The sea otter has a very thick, soft, woolly fur, and is most highly prized by the Russians and Chinese, to whom most of the skins are exported. In its habits it is allied to the seal, but has never been met with in large numbers. It is found in the North Pacific, from Kamschatka to the Yellow Sea on the Asiatic coasts, and from Alaska to California, on the American coast.

The annual production is about 1,000 skins, of which

100 are imported into this country by the Hudson's Bay Company.

**Seal** (*Phoca*).—There are numerous varieties of these animals, some of which are found on the western coasts of Scotland, Ireland, and Wales. They frequent, in immense numbers, the coasts of Newfoundland, Greenland, and Labrador, and the importations into this country frequently exceed 500,000 in one season. The young seals of some species increase in size with great rapidity, and it is asserted by the seal fishers that they double their bulk in eight days. The greater portion are tanned and enamelled with black varnish for ladies' shoes; other descriptions are well adapted for fur, especially the seal of the South Seas and the north-west coast of America. Before they can be used as a fur, it is necessary to remove the very coarse hairs which cover a beautifully fine and silky fur. The roots of these hairs are deeply seated in the substance of the thick pelt, while the fur is strongly attached to the upper surface of the skin. By shaving the pelt to half its natural substance the roots of the coarse hairs are cut through, and they easily fall out; but the same effect is produced by a natural process of fermentation, which ensues when the skins are properly prepared and allowed to remain together. The soft curly fur of the seal is now rarely used in its natural state, but is dyed a deep Vandyke brown, and has the appearance of the richest velvet.

**Fox**.—Of foxes' skins brought to this country there are many varieties; the black and silver foxes (*Vulpes fulvus*, var. *argentatus*) from the arctic regions are the most valuable. Many of the skins in the Exhibition are worth from 10 guineas to 40 guineas. They are purchased for the Russian market, being highly prized in that country. The cross and red foxes (*Vulpes fulvus*) are used by the Russians, Turks, and Greeks for cloak-linings and collars. The blue and white foxes are used in this and other countries for ladies' dresses. The white foxes (*Vulpes lagopus*) are represented by arctic voyagers as exceedingly numerous, and migrating in troops over the frozen seas at the approach of the rigorous season. They are easily caught, fifteen having been taken from one trap in four hours.

**Wolverine** (*Gulo luscus*).—This animal, which is only met with in North America, Norway, and Sweden, is now generally considered by zoologists as identical with the glutton of old writers. It is extremely mischievous to the fur-trader, and will follow the marten-hunter's path round a line of traps extending forty or fifty miles, merely to come at the baits. The fur is generally dark nut-brown, passing, in the depth of winter, almost into black, and is chiefly used in Germany and other northern countries for cloak-linings.

**Bear** (*Ursus*).—There are several descriptions of bear skins used by the furrier. The skin of the black bear of North America (*Ursus Americanus*) is used in this country for military purposes, for rugs, and carriage hammer-cloths. In Russia it is frequently manufactured for sleigh coverings, and the skin of the cub bear is highly valued for trimmings and coat-linings. That of the grey bear (*Ursus ferox*) is applied to similar uses. That of the white polar bear, of which the supply is very limited, is frequently made into rugs, bordered with the black and grey bear skins. The fur of the brown or Isabella bear (*Ursus subellinus*) has frequently been very fashionable in this country, when its value has been tenfold the present price. It is still considerably used in America for various articles of ladies' dress.

**Hare**.—The wool or under fur of the European grey hare (*Lepus timidus*) is extensively used for manufacturing felt hats, both in Europe and America. A few of these are dressed for the purpose of being worn as a protection to the chest.

The white hare of Russia and the polar regions (*Lepus glacialis*) was formerly much worn in its pure white state as a lining for ladies' cloaks, and as a substitute for the white fox, but the skin being exceedingly tender, its use for this purpose has been discontinued. The white hare is also frequently dyed; it looks exceedingly rich, but is not very durable.

**Rabbit** (*Lepus cuniculus*).—The English rabbit, both in

its wild and domestic state, affords a very plentiful supply of useful fur. When dressed and dyed in imitation of other skins, it is manufactured into a great variety of cheap and useful articles for the middle classes. The wool has recently been manufactured into a peculiar cloth adapted for ladies' use, but by far the greater number of skins are still used for hatters' purposes. The English silver-grey rabbit was originally a breed peculiar to Lincolnshire, where great attention was paid to it; but warrens have since been formed in various parts of the country. Skins of this variety are continually exported to China and Russia, where they are much esteemed, and command a comparatively high price. The Hudson's Bay rabbit is beautiful in the length and texture of its fur, but the skin is so fragile, and the fur so liable to fall off with slight wear, that it has little value as an article of dress. The white Polish rabbit is a breed peculiar to that country; its skin is often made into linings for ladies' cloaks, and being the cheapest and most useful fur for that purpose, the animal is imported in great numbers.

**Squirrel** (*Sciurus vulgaris*).—This attractive little animal abounds in most countries, especially in Siberia and the north of Europe. It is from the Russian dominions that we derive our principal supply of the skins of this agile creature, which exceeds in number that of any of the fur-producing animals. It is said that 15,000,000 are every year captured in Russia, our supply from thence exceeding 3,000,000 annually. The fur of the squirrel, of which there are several varieties, is light, warm, and durable; some of the lighter colours are dyed in imitation of sable. The colour of the Siberian squirrels varies from a pearl grey to a dark blue grey: the under parts, which are white, are frequently cut out and made into cloak-linings, remarkable for their lightness: the tails are manufactured into boas for foreign markets; they are also extensively used in the manufacture of artists' pencils.

**Chinchilla** (*Chinchilla lanigera*).—There are two chief varieties of chinchilla, the produce of South America: those from Lima are short in the fur, and inferior in quality to those from Buenos Ayres and Arica; the colour is a silvery grey, Arica producing the darkest and best-coloured skins. The general appearance of the animal places it between the squirrel and the rabbit: in its natural abodes it has the agility of the former, and resembles the rabbit in living in holes and burrows. The extreme softness and delicacy of the fur adapt it only for ladies' use. Though much admired and frequently worn in this country, it is more extensively consumed in France, Germany, and Russia.

**Raccoon** (*Lepus lotor*).—The racoon is an inhabitant of North America: the skins are imported into this country in immense numbers; but meeting with no demand for our home trade, are re-exported by merchants who purchase them at the periodical sales. They are used throughout Germany and Russia for lining shubes and coats, and, being of a durable nature and moderate in price, are esteemed as one of the most useful furs.

**Common Badger** (*Meles vulgaris*); **American Badger** (*Meles laboratorica*).—The skin of the European badger, from the wiry nature of its hair, is generally used for the manufacture of superior kinds of shaving brushes; but the skins exported from North America have a soft, fine fur, which renders them suitable for many purposes for which the larger furs are used.

**Cat**.—In Holland the cat (*Felis domesticus*) is bred for its fur; it is fed on fish, and carefully tended until the fur arrives at its greatest perfection; large numbers are also collected in England and many other countries. The wild cat (*Felis catus*) is much larger and longer in its fur, and is met with in extensive forests, particularly in Hungary; the colour is brownish grey, mottled, and spotted with black. The softness and durability of the fur render it very suitable for cloak-linings, and it is also made into wrappers for open carriages and railway travelling.

**Canada Lynx** (*Felis Canadensis*); **Lynx Cat** (*Felis Rufa*).—The fur of the lynx is long, soft, and of a greyish colour, sometimes, as in the Norway lynx, covered with brown spots; the belly is white, silky, and not unfrequently spotted with black. The change of fashion has for some time discarded it from this country; but it is

dyed, prepared, and exported in considerable quantities for the American market, where it is much valued and admired. It is generally used for cloaks, linings, and facings, for which purposes it is very appropriate, being exceedingly soft and light.

Furs are subject to injury by several species of moths, whose instincts lead them to deposit their eggs at the roots of the fine hair of animals.

Linnaeus mentions five species that prey upon cloth and furs, of which *Tinea pellionella*, *T. vestimentella*, and *T. tapetzella* are the most destructive. No sooner is the worm hatched than it eats its path through the fur, and continues increasingly destructive until it arrives at its full growth, and forms itself a silken covering, from which in a short time it again emerges a perfect moth.

Another cause of the decay of furs is the moisture to which they are frequently exposed; the delicate structure of the fine under-fur cannot be preserved when any dampness is allowed to remain in the skin. This fact is well known to the leather manufacturer, who, having wetted his skins, allows them to remain in a damp cellar for a few days for the purpose of removing the hair, which is pulled out with the greatest facility after remaining only one week in a moist condition. It follows from these observations that to preserve furs it is necessary to keep them dry, and to protect them from moths; if exposed to damp or rain, they must be dried at a moderate distance from the fire; and when put by for the summer should be combed and beaten with a small cane, and very carefully secured in a dry brown paper or box into which moths cannot enter. During the summer they should be examined once a month to be again beaten and aired, if the situation in which they have been placed be at all damp. With these precautions, the most valuable furs may be preserved uninjured for many years.

The Jury award Prize Medals to the following Exhibitors in this department:—

HEVINGTONS and MORRIS, King William Street, London (332, p. 535), for a collection of good and well-manufactured furs and skins, both natural and dyed, of stone marten, black marten, Kolinsky, sable, and ermine.

CLARKE, ROBERT, and SONS, Cheapside, London (307, p. 534), for a well-assorted collection of manufactured furs in ermine, mink, musquash, grebe, and seal.

CENTRAL COMMITTEE, NOVA SCOTIA (2, p. 970), for a choice collection of skins, the produce of Nova Scotia, fully described in Illustrated Catalogue, with the names attached to the specimens.

DRAKE, R., Piccadilly, London (306, p. 534), for three very beautiful muffs made from the choicest skins of the Russian sable, the grebe, and miniver.

EAGERS, F., Moscow, Russia (not in Catalogue), for a fur carpet, well designed, and of good workmanship.

GEYER, J., Pesth, Hungary (346, Austria, p. 1024), for a national cloak called the *Bunda*, made from Hungarian lamb skins; the tanned leather, which is richly embroidered, forms the exterior of the cloak.

HUDSON'S BAY COMPANY, Fenchurch Street, London (301, pp. 529-534), for a choice collection of fur skins, the produce of their possessions in North America, consisting of twenty-seven groups, which are fully described in the Illustrated Catalogue, with their scientific names.

KEILICH, HENRY, 9, Butterland Street, Hoxton, London (not in Catalogue), for models of a miniature tigress and cubs, displaying great ingenuity and excellence in design and workmanship, each hair of which is said to have been separately fixed by the hand.

KÜNTZ, L., Berlin (139, Prussia, p. 1056), for a camaille of superior workmanship, made entirely from the tails of the mink.

MEYER, M. and S., Bow Lane, London (304, p. 534), for a variety of manufactured articles made from the skins of the rabbit, and dyed in imitation of more costly furs, by which a cheap, warm, and ornamental clothing is brought within the means of the working classes.

RUSSIAN IMPERIAL CABINET, St. Petersburg (not in Catalogue), for a pelisse lining made from the necks of

the silver fox, for a Russian sable lining, and for skins of the same animal, from Kamschatka.

SMITH, GEORGE, and SONS, Watling Street, London (310A, p. 534), for an assortment of good and well-manufactured furs made from Russian sable, North American sable, chinchilla, ermine, and squirrel.

TURKEY, HIS HIGHNESS THE SULTAN OF (1, Turkey; p. 1387), for a large and interesting collection of skins, the produce of Turkey.

WARMING, M., Copenhagen (7, Denmark, p. 1356), for a fur carpet, with stuffed foxes serving as footstools, in which the design and workmanship are in good taste.

WEINKNECHT, T., Brussels (259, Belgium, p. 1159), for two carpets made of fox skins and other furs, beautifully designed; also for a choice collection of other furs.

ZEITZ, J. F., Berlin (841, Prussia, p. 1096), for a coat-lining made entirely from mink tails, and for a similar article made from the paws of the fisher (*Lutula Canadensis*). Both specimens show great skill in manufacture.

The Jury make Honourable Mention of the following Exhibitors:—

BOLDNER, S. (not in Catalogue), for a fur hearth-rug representing the Royal Arms of England.

DICK, A., 35 George Street, Edinburgh (311, p. 534), for a well-manufactured hearth-rug of many pieces of fur neatly and artistically arranged.

HENDERSON, J., Montreal (107, Canada, p. 965), for sleigh robes and other furs, the produce of the colony.

LIVERPOOL LOCAL COMMITTEE, per T. C. ARCHER (270, Class XXIX., p. 803), for specimens of the various skins imported into Liverpool, methodically arranged, and with their scientific names attached. (Awarded a Prize Medal by Jury of Class XXIX.)

#### Feathers.

The beautiful colouring and graceful forms of these ornaments have always attracted general admiration, which the closest inspection tends only to increase. Whether our attention is drawn to the soft delicacy of the down of birds, or to the mechanical structure of the pinion feathers, which combine the greater strength with lightness, they are equally interesting and instructive.

The kinds which are used for dress are those of the ostrich, the marabout stork, the rheu or American ostrich, the emu, the osprey, the egrette, the heron, the antrenga, the birds of Paradise, the swan, turkey, peacock, argus pheasant, ibis, eagle, grebe, &c.

The feathers of the ostrich, of which there are several varieties, all varying in texture and quality according to climate and food, are imported into this country from Mogador, Aleppo, Alexandria, and the Cape of Good Hope, and have been used in all ages as ornaments of the head. They formed the plumes of knights' helmets, and were much used by our nobility in the reign of Henry VIII., who himself wore one on state occasions. The black ostrich feathers have been used for many years by the Highland regiments, and at funerals. The feathers in their natural state are still worn by the natives of the Cape of Good Hope, where it is not uncommon to see a waggoner's hat ornamented with them. The perfection to which the art of dyeing has been brought in this country and in France, and the great improvement in their manufacture in other respects, has brought them extensively into wear for bonnets and head-dresses.

Next in request to the feathers of the ostrich are those of the marabout stork, which are of two kinds, white and grey. These are imported into this country from Calcutta in great quantities. They are very much admired for their beautiful texture and extreme lightness, and are used for head-dresses, muffs, and boas. The white kind have at times been so scarce as to be worth their weight in gold.

The feathers of the rheu, or American ostrich, are usually imported from Buenos Ayres. They are used for a variety of purposes by the natives, who dye them of different colours, and form head-dresses and coverings for the body. The glossy kinds are used for military

plumes in South America and in Europe, and the long brown feathers of the wing are made into brooms and dusting brushes.

A very graceful plume is made from the feathers of the emu, which are much prized on the Continent, and worn there both of their natural colour and dyed. The feathers of the osprey and the egrette, which are found in various parts of the globe, are chiefly used for military costumes by hussar regiments: those of the smaller egrette, which are the most graceful, are worn by ladies.

The feathers of the Indian heron and the antrenga are much prized on account of their scarcity, and are frequently worn by eastern princes.

Birds of Paradise, which are imported from the Manilla, have in all ages been in great request as ornaments both for men and women, and were formerly very rare. They are favourite decorations for the Turkish turban, and it will be remembered that they were worn by the Nepaulese princes when in this country.

The feathers of the common cock are also used for ladies' riding hats and for military plumes. The greater part are imported from Hamburg. The down of the turkey, the swan, and the goose, is made into plumes, muffs, and tippets; and from the feathers of the ibis, wreaths and trimmings are formed, which are much admired for the brilliancy of their colours.

The manufacture of feathers gives employment to a great number of females, and is principally confined to England and France, although of late manufactories have been established at New York for goods suitable for that country.

The Jury award a Prize Medal to the undermentioned firm:—

ADCOCK and Co., 3 Princes Street, Cavendish Square, London (323A, p. 534), for an admirable collection of the most beautiful kinds of feathers, manufactured and dyed for ornamental purposes.

The Jury desire to make Honourable Mention of the following Exhibitors:—

BOOTH, J. P., Cork, and 80 Hatton Garden, London (112, p. 533), for various articles of ladies' dress made from turkey-down and feathers.

FOSTER, SON, and DUNCUM, 16 Wigmore Street London (74, Class XXIX., p. 795), for a handsome muff and boa of marabout feathers.

HENOC, 1 Rue St. Sauveur, Paris (261, France, p. 1189), for screens and feather-brooms made of ostrich, peacock, and other feathers.

L'HUILLIER, E., 86 Rue St. Martin, Paris (1325, France, p. 1239), for various kinds of feathers for ornamental purposes, head-dresses, cloaks, screens, &c.

LODGE, A. A., 50 Rue Bourg L'Abbé, Paris (1329, France, p. 1240), for plumes of feathers and screens of various kinds.

PERROT, PETIT, and Co., Rue de la Bourse, Paris (852, France, p. 1225), for two rare and magnificent Persian heron plumes and other fancy feathers for dress. (Awarded a Prize Medal by Jury of Class XXIX.)

TOLLIT, GEORGE, Betley Hall, Staffordshire (154, Class XX., p. 586), for tippets, cloaks, victorines, and muffs made from goose-down and feathers: a manufacture established with the view of giving a new employment to needle-women.

#### Artificial Hair.

The material for this trade, which gives occupation to a large number of manufacturers and workmen, is procured from the north of France, Belgium, and Germany, and some of good quality is occasionally brought from Ireland. The lighter-coloured hair, which bears the highest value, is the production of Germany; the darker shades are imported from France. The wholesale price varies from 30s. to 60s. per lb., and occasional rare specimens are of much higher value. A head of hair, such as is bought of the peasant girls in the districts before named, weighs from 1½ to 3 of a lb., and is usually exchanged for trinkets or articles of dress.

The Jury, after carefully examining all the specimens contributed by various Exhibitors, have selected the following, of which to make Honourable Mention, as the most suitable recognition of the general equality in style and excellence displayed in these productions:—

BOUCHET, C., 74A New Bond Street (246, p. 527), for specimens of the new crochet-work in wig making, on skin and on net.

BROWNE, F., 47 Fenchurch Street, London (245, p. 527), for head-dresses of ornamental hair.

CARLES, H. R., 45 New Bond Street, London (251, p. 528), for wigs and head-dresses.

CAUSSE, D. A., 267 Regent Street, London (259, p. 528), for perukes and head-dresses.

CROISAT, J., 76 Rue de Richelieu (1574, France, p. 1252), for perukes without toupées, produced by machinery.

ISODORI and BRANDT, 217, Regent Street, London (253, p. 528), for wigs, perukes, and other works in hair.

ROBEY, W., Richmond, Surrey (262, p. 528), for ladies' head-dresses.

THIRMEZGE, 4 Rue Vide Gousset, Paris (695, France, p. 1212), for perukes and ladies' fronts.

TYZACK, W. V., Norwich (264, p. 528), for specimens of manufacture in false hair.

WINTER, W., 205 Oxford Street, London (249, p. 528), for wigs and head-dresses.

The Jury are much indebted to Mr. NESBITT, Wigmore Street, to Mr. JENNINGS, Quadrant, and to Mr. DALLING, Old Bond Street, for their valuable assistance in the examination of the various manufactures in artificial hair.

#### *Woven Hair for Furniture and other purposes.*

Hair used for weaving consists of the long hair from horses' tails. It is procured principally from South America and from Russia. All the black and grey hair is dyed for the manufacture of black hair-cloth for covering furniture. White only can be dyed so as to produce what are called fancy colours, such as green, claret, crimson, scarlet, &c., and great care is required in the process, which, however, when well managed, produces good permanent colours.

The quality of the cloth, as well as the brilliancy and permanency of the colours, depend also in a great degree on the nature of the warp, which may be either of cotton, linen, or worsted. Coloured hair-cloth (principally manufactured at Worcester, Sheffield, and Paris) has been extensively used in the fitting up of steam-vessels, and for covering chairs, sofas, railway carriages, &c. Some of the lighter colours have also been used for boys' caps, slippers, &c.

In the manufacture of hair-cloth, the weaver uses a sort of hook-shuttle, which he passes between the threads of the warp, or shed, towards his left hand; the assistant, or "server," places a single hair over the end of the hook, and the weaver draws it through the warp. This operation is a tedious one, and the hairs being necessarily placed in singly, prevents the application of machinery, which is so advantageously used in fabrics where the shoot or weft consists of a continuous thread.

In this department, the Jury award Prize Medals to the following Exhibitors:—

DELACOUR, H. P., 47 Rue Vieille du Temple, Paris (472, France, p. 1200), for horsehair and "vegetable silk" damask.

FORNER, A., 136 Regent Street, London (99, Class XXIII, pp. 889-90), for ornaments worked in hair and gold.

HAUSMANN-HAF, B., Velvorde, Brussels (257, Belgium, p. 1159), for horse-hair fibre stuffing for furniture, and other manufactures in hair.

LAYCOCK and Sons, Sheffield (830, p. 535), for horse-hair damask, &c., of superior manufacture.

LEMONIER and Co., 1 Rue du Coq-St. Honoré, Paris (909, France, p. 1243), for ornamental hair-work.

WEBB, E., Worcester (243, p. 527), for coloured hair-cloth and cloth composed of silk and hair; also for horse-hair carpets, woven in the same manner as Brussels

carpets. In all these articles great excellence of manufacture has been attained.

WISDOM, RUSSELL, and WHITMAN, Cleveland, Ohio, America (205, United States, p. 1450), for superior specimens of curled hair for furniture.

#### *Leather.*

An exhibition of the various descriptions of leather brought from every country, affords an opportunity of comparing the peculiar qualities and excellencies of each, which must be highly instructive both to manufacturers and artisans. Many of the improvements in this branch of trade have been introduced from other countries, where they have originated in causes purely local: thus, Russian leather, so much esteemed for its scent, is tanned with the cheapest bark of the country, and softened with an oil extracted from the bark of the birch tree, also abundantly produced; the combination of these materials gives the scent and qualities so highly valued in Russian leather. The peculiar softness in French curried leather is in part attributable to using the bark of the evergreen oak, with which the better descriptions are tanned; and the sole leather of England, which is not surpassed by any of its class, is dependent, to some extent, upon the superior oak bark that abounds in our island.

The bark of the oak tends to give firmness and solidity, while other sorts are remarkable for the softness they impart to the leather; and each material used in tanning gives some distinct quality in respect to colour, scent, toughness, or capability of resisting moisture and decay.

Experience shows that the tanning principle in different combinations is found in the bark and leaves of many trees; and it is to be expected that an extended comparison of the various descriptions of leather, for the first time brought together, will be the means of suggesting many improvements.

Chemistry has hitherto done less in this branch of manufacture than might have been expected. Though numerous experiments have been tried, and many patents granted for new processes, there has been no decided improvement, no marked progress, to show that better results have been obtained than by the old methods of tanning.

Very much has, however, been effected by mechanical means during the last 50 years. The steam-engine has been generally introduced into the manufactories of the leather-dressers and tanners. It is used in grinding bark, for softening foreign hides, and in giving motion to many machines for washing, glazing, and finishing leather. But the most important results have arisen from the invention of very ingenious machinery for splitting hides and skins. These machines completely separate the upper from the under surface, leaving each part of the same superficial dimensions as the original hide. This is effected by means of a long sharp knife, kept in rapid motion about the sixteenth of an inch from the edge of a smooth bar of iron, over which the skin is drawn by a revolving cylinder. By another machine the skin is pressed between two revolving rollers, and presented, as it emerges to the edge of a long straight knife, which is nicely adjusted between the upper and under surface of the skin, and kept in motion backward and forward to facilitate the operation of splitting. These machines are now common in most of the leather manufactories of England, and in some of the most important establishments on the Continent.

The hydraulic press is found to be a very useful auxiliary for expressing the grease from sheep skins; it enables the leather manufacturer to dye more brilliant colours, which cannot be well done while any grease remains in the pores of the skin. By these appliances the tanners and leather-dressers are enabled to produce a more perfect and a cheaper article. The improved facilities of transport, the abolition of excise duties, and the greater freedom of our commercial relations with other countries, have all tended to the same desirable result.

We proceed to give a short account of several descriptions of skins used for tanning and leather-dressing; specimens of which are met with both in the English and Foreign sections of the Exhibition.

*Horse Hides.*

Horse hides are brought into this country in large numbers; the principal supply is from South America, from whence 180,000 were imported last year. The horse was unknown in South America previous to the occupation of the country by the Spaniards; it now runs wild over the flat plains of that country, and is caught for the value of its hide and hair. These skins are usually appropriated for ladies' shoes, either as cordovan or enamelled leather; for the latter purpose, the hide is split by a machine described in another part of this Report. The price of these hides varies considerably; at the present time the value is very low, not exceeding 4s. 6d. each.

*Ox and Cow Hides, and Calf Skins.*

Ox and cow hides are produced in very large numbers in the British Isles; they are usually tanned in oak bark, and appropriated for sole-leather, as well as for harness, machinery, and coachmakers' use. Foreign hides, which are imported largely from the East Indies, South America, and the Cape of Good Hope, are similarly appropriated. The latter description, like most of the skins from that fertile colony, are large, thick, and well grown. A remarkable specimen of the horns of the Cape ox, measuring more than 8 feet across, is exhibited in the department appropriated to Cape produce. The calf skins of England are very generally tanned in oak bark, and used for the upper part of boots and shoes. Foreign calf skins are imported from the Baltic, where they are killed much younger than in this country, and are used for bookbinding, for gloves, and ladies' shoes.

*Hippopotamus Hides.*

About 100 of these hides have been annually imported into London from South Africa; they have been tanned in oak bark, in which state they make exceedingly thick and compact leather: no very suitable application has yet been found for them.

*Deer Skins.*

Deer skins produced in this country are manufactured into oil or chamois leather, and appropriated for gloves, breeches, boots, and braces. A very large number are annually collected in North America, and manufactured in the United States. A small portion of these skins are used in this country and in Germany. The hair of the deer is said to be the best material for stuffing saddles.

*Hog Skins.*

Hog skins are collected and tanned almost exclusively in Scotland, where it has long been the custom to strip the skin from the carcase of the animal, contrary to the practice in this country and in Ireland. The leather is porous and light, but extremely tough and strong on the grain or outer surface. When tanned and curried, it is sold to harness-makers for covering saddles, for which purpose it is peculiarly adapted. The wild boar is remarkable for the extreme thickness of its hide on the back and mane, which enables it to break through the thorny brushwood of the forests with facility. A specimen of this part of the skin is exhibited by Mr. Geo. Edwards, which is more than two inches in thickness, and took seven years to complete the process of tanning.

*English Sheep and Lamb Skins.*

The immense supply of English sheep skins affords occupation to many large establishments, in which they are manufactured and variously coloured similar to morocco leather. They are tanned in bark for bazils, in alum and salt for white leather, and are also largely appropriated for parchment and chamois leather. The principal places where the skins are dressed and dyed are Bermondsey, Leeds, and Manchester, whence they are exported to Germany, South America, and our own colonies. A considerable quantity are also sent to the United States, after being partially prepared and salted. The value of an English sheep pelt varies from two to ten pence, when the wool of the same skin may be estimated from two to ten shillings; hence the attention

which is paid to the latter, while the former is entirely neglected. In proportion to the fineness of the wool, the compactness and value of the pelt are depreciated. The supply of sheep and lamb skins annually produced in London and its vicinity exceed a million and a half; a large portion of these are split; the upper surface is tanned with sumach; the lower half is manufactured into parchment and chamois leather. Of lamb skins, the grain or upper surface is frequently made into white leather for tying over the stoppers of chemical bottles; the flesh, or lower surface, is dressed into thin chamois leather for lining gloves.

*Cape of Good Hope Sheep Skins.*

A very distinct variety of sheep skin is imported from the Cape of Good Hope; the wool is short and coarse, and rarely produces more than 1 lb. per fleece. This sheep has a tail of extraordinary thickness, frequently as large as the neck of the animal, and loaded with fat. Though the wool is of no value to the Cape farmer, this animal is still preferred by some flock-masters in consequence of the superior quality of the meat, the large quantity of fat produced, and the hardy constitution of the sheep, which appears to be particularly adapted to the climate. A similar sheep skin with broad tail is also imported from Smyrna; but on this the wool is of finer quality. When manufactured into leather, the quality of the Cape sheep skin is found to be nearly equal to morocco leather: it is frequently dressed for tan driving gloves, and produces a very serviceable and durable article.

*Foreign and English Lamb Skins for Gloves.*

In Italy, Spain, and the south of France, it is the custom to kill the lamb at a much earlier period of its growth than is usual in England; the skin is in consequence small, fine, and thin, and is used as a substitute for kid: the leather, however, is neither so strong nor so glossy on the surface, but sufficiently soft and elastic, and largely manufactured into gloves in the counties of Somerset and Worcester. About 1,400,000 lamb skins are annually imported for this purpose. Those of the highest value are brought from the vale of the Arno, in Italy; they are also imported from Turkey, Austria, Spain, and France. Small English skins, which are taken by the shepherds from the lambs that die within a few days of their birth, are frequently dressed with the wool, and appropriated for lining gloves and shoes. About 400,000 of this description are annually collected, and a portion of them are manufactured into coloured leather gloves.

*Swiss Goat Skins.*

The goat is reared in considerable numbers in Switzerland, Italy, and the south of France, for the valuable milk which it supplies. The skins are preserved with great care, and exported to this country for the purpose of making into morocco leather. Those from Switzerland bear the highest value, on account of the perfect nature of the grain of the skins, which enables the morocco manufacturer to dye them very brilliant and permanent colours. The texture of goat-skins is very strong, and more durable than the sheep; from which circumstance they are well adapted for covering chair-seats and lining carriages. About 96,000 are annually imported from Switzerland and the valley of the Rhine.

*Cape Goat Skins.*

Skins of the Cape goat are much thicker than any other kind, and are applied to purposes where great strength and substance are required. The body of the animal is as large as the fallow deer. Many of the skins are exported to Germany, where they are manufactured into leather for the common dresses of the peasantry.

*Mogadore and East Indian Goat Skins.*

Mogadore goat skins are distinguished by the great length of the hair, which, when shorn from the skin, is curled and manufactured for stuffing chair-seats and mattresses. The skin is rather inferior in quality, and usually

made into black morocco, which, from the circumstance of our first supplies having been derived from Spain, still retains the name of black Spanish leather.

East India goat skins are small in size and extremely short in the hair: they are appropriated for ladies' shoes, and occasionally dyed for covering chair-seats.

#### *Kid Skins.*

Kid skins are collected in the south of France, Germany, Switzerland, Italy, and Ireland. French skins are the most perfect, and of the finest quality; those from Ireland, of which there are 60,000 skins annually exported, are also highly valued. East Indian kid skins are adapted for light shoes, but are occasionally made into gloves. As soon as the kid begins to feed on herbage, the fineness and delicacy of the skin are injured, and the skin becomes unsuited for the best gloves; it is then used for shoes, braces, and binding-leather, for which purposes it is well adapted on account of its great strength and elasticity.

#### *Seal Skins.*

The seal has been already mentioned among the fur-producing animals; the particular species whose skins are manufactured into leather are found in great numbers on the shores of North America, from Newfoundland to the Arctic Ocean. As many as 600,000 have been caught in one season, and a large fleet of vessels is employed in this trade. The oil which the animal produces is the principal inducement to its capture; but the skin, which is worth from 3s. to 4s., forms no inconsiderable sum when estimated upon the large numbers that are brought to this country. The seal, when young, has long, white, silky hair, which it sheds in a few weeks, and becomes covered with hair of a coarser and darker colour. In the latter state it is best adapted to the purposes of the leather-dresser. When carefully manufactured, the skin has greater strength in proportion to its substance than any leather that is usually worn. It is generally made into black enamelled leather for ladies' shoes, and is much used for shoe-binding, where great strength is necessary. From experiments tried on seal, porpoise, and whale leather, that are exhibited in the Canada department, it appears probable that the skins of the marine mammalia have greater strength than those of land-animals.

Skins and furs in the undressed state are liable to be eaten through by the grub of a small beetle (*Dermestes vulpinus*). The eggs are generally deposited in some crevice about the head of the skin. These produce a swarm of hairy grubs, which feed upon the pelt, and grow to the size of small caterpillars. Instances have been known where the entire value of a foreign package of skins has been destroyed by these insects, and the annual loss occasioned by them in this country is computed to be from 2000*l.* to 5000*l.* They are found to be most destructive when skins are packed in midsummer or autumn, at which season the insect flies abroad and deposits its eggs unperceived as the skins are drying in the air. The collections of skins packed in spring and winter are not liable to this injury. Camphor and tobacco-leaves have been tried against the depredations of this insect, and each has been attended with some success, but not so entirely as to recommend either of them as a complete preventive.

#### *Rough Tanned and Sole Leather.*

The number of exhibitors in this subdivision is 53, of whom 15 are in the English department, 9 in the French, and 29 in other sections of the building.

The sole leather in the English department has for the most part been tanned with oak bark, but we notice some varieties in the collection of Messrs. BOUTCHER, MORRIS, and Co., and in the Australian division, in both of which there are specimens that have been tanned with mimosa bark. The Hon. Z. PAATZ, of Prattsville, New York (102, United States, p. 1440), exhibits leather tanned with the bark of the horlock tree: several exhibitors have employed valonia as a principal ingredient. In the New Zealand collection there are some remarkable va-

rieties; and in the Russian department we find specimens said to be cured with rye.

Although many vegetable extracts have been discovered which are useful in tanning, inasmuch as they shorten the process and economize the cost of production, yet no material has yet been found which combines so many valuable qualities as oak bark for tanning sole leather; it fills more completely the pores of the hide, and prevents the great absorption of water to which leather tanned with other material is liable.

The simplest method of tanning sole leather, still practised in some of our colonies, is, to shave the hair from the hide with a sharp knife, and to steep the pelt in bark liquors for a year; by which time the gelatine of the hide has chemically united with the tannin, and the process is complete. In England it is customary to remove the hair by immersion in lime-water; if this process is carried beyond the proper point it dissolves too much the soluble gelatine, and renders the leather porous.

Since the abolition of duties on tanned hides and skins, a considerable increase has taken place in the importations from foreign countries, with obvious advantages to the foreign manufacturer and English consumer. Both curried and varnished calf leather of excellent quality are brought from France, Germany, and Switzerland, and large numbers of curried boot-fronts. From Australia and the East Indies arrivals of tanned leather are more frequent, and supply at moderate prices the increasing wants of the community. In many cases the economy of tanning on the site of produce is considerable: the labour and tanning materials are both procurable at less cost; much is saved by the diminished freight of the manufactured article; and the leather is less liable to damage by moth and worm, to which untanned skins are exposed in their passage to this country.

As many beautiful and well-manufactured leathers have come under the notice of the Jury, which have been exhibited by proprietors, or by those who have only to a small extent superintended the manufacture, the Jury have recognized the merit of these productions by including the exhibitors with those manufacturers whom they consider entitled to Honourable Mention.

The Jury award Prize Medals to the following Exhibitors:—

COX, W. H. and Co., Russell Street, Hermondsey, London (293, p. 529), for two foreign butts very well tanned.

CRAWFORD, H. M., Philadelphia (51, United States, p. 1436), for calf skins tanned in oak bark.

DRAPER, R. and H., Kenilworth (293, p. 529), for a remarkably heavy and well-tanned English hide, weighing 90 lbs.

DUPORT, V., 16 Rue des Francs Bourgeois St. Marcel, Paris (182, France, p. 1182-3), for three split hides of twice the usual length. The increase of surface is ingeniously obtained by a peculiar mode of splitting. A machine divides the hide into two surfaces, commencing at the neck and continuing nearly to the opposite extremity; where the splitting terminates the hide is neatly cut to preserve a uniform thickness, and when opened out extends from 17 to 18 feet.

FIEUX and Co., Toulouse (210, France, p. 1183), for well-manufactured sole and harness leather.

HEPBURN, JOHN and THOMAS, Long Lane, Hermondsey (293, p. 529), for an English crop butt, of good substance and texture, and well tanned in every respect.

LANDRON BROTHERS, Meung-sur-Loire (1639, France, p. 1255), for well-tanned sole leather.

PELTREAU, AUGUSTE, Chateau Regnault, Indre-et-Loire (677, France, p. 1214), for sole leather of excellent quality, tanned by two methods.

PELTREAU, F. jun., Chateau Regnault, Indre-et-Loire (949, France, p. 1225), for sole leather of excellent quality, tanned in oak bark; some of the specimens have been tanned without the usual application of lime.

The Jury make Honourable Mention of the following Exhibitors:—

BRAUCHAN DE BARÉ, A., Namur (263, Belgium, p. 1159), for tanned hides, applicable for soles and pump-buckets.

BOUTCHER, MORTIMORE, and Co. (293, p. 529), for tanned sole leather.

BUCKNALL, GEORGE (293, p. 293), for tanned hippopotamus hides of remarkable thickness.

BUSCHMANN, J. W., St. Vith 1886, Prussia, p. 1072), for well-manufactured sole leather.

ESTIVANT BROTHERS, Givet, Ardennes (1214, France, p. 1235), for a Buenos Ayres hide, tanned in oak bark.

EVERSHED, Sussex (293, p. 529), for well-tanned light sole leather.

HAUSER, J. de J., Waedenschwy, Canton Zurich (172, Switzerland, p. 1277), for a specimen of sole leather, tanned in oak bark.

HOLMES, T., Hull (16, p. 518), for specimens of the tanned hide of the walrus, and polishing wheels covered with the same; also for stuffed heads of the male and female walrus, taken at the Davis' Straits fisheries.

KILSEY, J. T., Lingfield, Sussex (266, p. 528), for a well-tanned crop hide, weighing 82 lbs. The process of tanning occupied two years.

MASSON, CHARLES, Huy (267, Belgium, p. 1152), for tanned sole leather of good quality.

#### *Curried Leather.*

Leather, having been first tanned and dried, requires to be reduced to an even substance, to be well extended, and made supple with fat or oil, before it is fit for the upper part of boots. In the latter operations consists the art of the currier; and although much of the strength of the leather depends upon the previous treatment, still great attention and judgment are required to conduct this process perfectly. No article enters more generally into the consumption of the affluent and labouring classes; and it is evidently a subject of some importance to adopt those methods of currying which secure the greatest suppleness of leather, combined with durability.

The manufacturers of France have for many years excelled in their mode of tanning and currying the finest descriptions of calf leather: those from the south of France (Bordeaux calf), which are reported to have been tanned with the bark of the evergreen oak, are extremely soft and pliable, and their merits are obvious from the extensive sale they meet with in this country. The mode of tanning and currying pursued by the English exhibitors is adapted to bear exposure to wet, and great improvement has taken place in the method of rendering the leather soft and easy to the wearer. The Swiss exhibitors have shown some very excellent leather of this class, for the upper parts of boots and shoes.

There are upwards of 70 exhibitors of curried leather, of whom 20 are in the French division, 13 in the English, and the remaining 44 are distributed through every section of the Building.

The Jury award Prize Medals to the following Exhibitors:—

BOSSARD, I., Charch Street, Bermondsey, London (294, p. 529), for curried calf leather of superior qualities, combining great strength with softness and pliability.

COURTÈPE-DUCHESNEY, 11 Rue du Renard, St. Sauveur, Paris (806, France, p. 1219), for boot-fronts, very pliable, and of good quality, principally manufactured from the calf skins of Paris.

COZENS and GREATREX, Walsall, Staffordshire (283, p. 528), for tanned and curried leather, adapted for bridles, and for well-manufactured hog skins.

DEZADUX-LAOUB, Guise, France (167, France, p. 1181), for curried calf skins and well-tanned sole leather.

GUILLLOT, J. A., 17 Rue du Boulai, Paris (534, France, p. 1204), boot-fronts of various kinds, very well manufactured.

HEMSWORTH and LINLEY, West Smithfield, London (20, p. 519), for boot-fronts, and cordovan of excellent quality and workmanship.

HERRENSCHMIDT, G. F. Strasbourg (538, France, p. 1204), for boot-fronts, and curried calf-skins, soft in texture.

JETU, C. A., Quebec (109, Canada, p. 965), for curried porpoise leather, and samples of leather from the skin of the whale; the porpoise leather is of fine texture and con-

siderable toughness, and is remarkable as the first of the kind exhibited in this country.

LAMBERT and SON, Bermondsey New Road, London (63, p. 521), for waxed calf skin boot-fronts, and cordovan, of good qualities and workmanship.

PRIN, A., Jun., Nantes (1411, France, p. 1243), for russet and black curried calf leather, well manufactured.

MERCIER, J. J., Lausanne (178, Switzerland, p. 1277), for curried calf leather, boot-fronts, and chamois leather, well manufactured for the purposes to which they are applicable.

MERKLINGHAUS and WEX, Barmen (672, Prussia, p. 1087), for dressed hides manufactured for saddlery and harness.

SKVORSOFF, M., Moscow (232, Russia, p. 1374), for curried calf leather of good quality, and a few calf skins tanned and curried, with the hair attached as an inside lining for the boot; extremely soft and pliable.

STOCKIL, W., 33 Long Lane, Bermondsey, London (17, p. 518), for specimens of boot-fronts, very well curried from the English leather.

SUSER, H., Nantes, France (1022, France, p. 1227), for a good assortment of curried calf leather and boot-fronts.

VENTUJOL and CHASSANG, 21 Rue des Gobelins (1384, France, p. 1242), for boot-fronts manufactured from Bordeaux calf skins, remarkable for peculiar softness, fineness of texture, and the great toughness of the material.

The Jury make Honourable Mention of the following Exhibitors:—

BUDIN, R. A., Rue du Fer à Moulin, Paris (17, France, p. 1175), for curried horse hides, suited to the upper part of boots and shoes.

BUSE, N., Swansea, Wales (4, p. 518), for curried calf leather, well manufactured.

FORTIER BEAULIEU, Rue de la Lupette (510, France, p. 1203), for curried leather suitable for harness and saddlery.

GHEISLAIN-DUBOIS, Binche (469, Belgium, p. 1166), for cow hide curried for strap leather.

HOGARTY BROTHERS, Cork, Ireland (13, p. 518), for curried calf leather and boot-fronts, very well manufactured.

MASSEMIN, C. L., Rue de la Reyne, Paris (1345, France, p. 1240), for calf leather adapted for boot-fronts.

ONERCONZ, H., Trèves (383, Prussia, p. 1072), for curried leather, and for a well-tanned hide, a perfect imitation of Russian leather.

PAILLART BROTHERS, Rue du Grand St. Michel, Paris (338, France, p. 1193), for calf and sheep leather manufactured for straps and rollers.

REULOS, A. J., 13 Rue Geoffroy St. Hilaire, Paris (1434, France, p. 1244), for curried horse leather, adapted for boots and shoes.

SOUTHEY and Co., Lincoln's-Inn Fields, London (51, p. 520), for an extensive assortment of good leather, manufactured for coach and harness makers.

TAILLET, V., Brussels (254, Belgium, p. 1159), for boot and shoe leather, well manufactured.

WOOD, W. and S., 32 Bow Street, London (25, p. 519), for a well-manufactured assortment of calf skins, curried and dyed in imitation of Morocco leather.

#### *Varnished Leather.*

Varnished and enameled leather has been brought to great perfection during the last 25 years, and increases in general demand as the improvements in its manufacture become generally known. Though the difficulty of making a bright varnish adhere to leather which is required to bend freely, and retain an unbroken surface, is considerable, it has been successfully overcome by the use of boiled linseed oil, mixed with vegetable black and Prussian blue to deepen the colour. This composition (the consistence of a thick paste) is rubbed on to the surface of the leather by hand, and dried in a stove heated to 150 and 170 degrees Fahr. The operation is repeated from three to seven times, according to the nature of the leather, and when the varnish is thoroughly dry, it is

found to adhere very firmly, and to bear considerable tension without fracture.

Many coloured pigments are mixed with the varnish, without materially altering its tenacity: by this means the most brilliant colours are produced, and the leather is rendered more applicable for ornamental purposes.

The number of Exhibitors in this branch of the leather trade is thirty-three, of whom nine are Germans, seven French, four English, and thirteen from other countries.

Prize Medals are awarded to—

COURTOIS, E., 12 Faubourg Montmartre (1571, France, p. 1252), for black and coloured varnished calf hides, brilliant on the surface, and well manufactured.

DEADDE, J., 18 Boulevard de Charonne (813, France, p. 1219), for a large assortment of well-manufactured calf and cow hides, adapted for shoemakers and coach-manufacturers.

DIXON and WHITTING, Bermondsey, London (200, p. 529), for an assortment of varnished and enamelled hides and splits, adapted for coachmakers, &c. In this collection the practicability of splitting three surfaces from one hide, is shown by the exhibition of the three parts separately tanned and varnished.

DOERR and REINHARD, Worms (33, Hesse, p. 1128), for a good assortment of varnished calf leather for shoemakers.

GAUTIER, J., 4 Faubourg Montmartre, Paris (1244, France, p. 1237), for black and coloured varnished calf leather, on which the enamel is brilliant, and the leather sufficiently pliable.

HEINTZ and FREUDENBERG, Baden (382, Prussia, p. 1072), for black varnished calf leather, on which the enamel is strong and brilliant.

HEYL, C., Worms (32, Hesse, p. 1127), for varnished calf leather of excellent quality.

HOUEITE, A. and Co., 46 Rue du Fer à Moulin, Paris (1271, France, p. 1238), for a superior assortment of black and coloured varnished calf leather.

JORÉZ, jun., Brussels (306, Belgium, p. 1160), for a white varnished hide of superior quality, and for well-manufactured curried leather.

MAYER, MICHEL, and DENINGER, Mayence (36, Hesse, p. 1128), for japanned and varnished hides, and calf leather, and for morocco, roans, and skivers, dyed in great variety of colour. These Exhibitors also show curried leather for harness, and other purposes. Each description of leather has been well manufactured.

NYSET and Co., 132 Faubourg du Temple, Paris (1373, France, p. 1243), for black varnished calf leather, manufactured very perfectly for boots and shoes. The varnish is brilliant, and sufficiently strong and elastic to bear the bend and strain to which it is liable.

OASTLER and PALMER, Bermondsey, Loffdon (286, p. 529), for a large assortment of enamelled and varnished leather for coachmakers, and for a very well tanned crop butt.

The Jury make Honourable Mention of the following Exhibitors:—

HALL, Sydney, New South Wales (not in Catalogue), for enamelled kangaroo skins, manufactured for boots and shoes.

MAYER, IGNAZ Munich (46, Bavaria, p. 1100), for varnished calf and very good enamelled coach hides.

MINOPRIO and HOEWIENNER (37, Hesse, p. 1128), for varnished calf and coloured japanned hide.

ROTH, C. W., Frankfurt (9, p. 1122), for varnished calf leather.

VIGNAUX, L. J., Barcelona (249A, Spain, p. 1344-45), for varnished calf leather, suitably manufactured for boots and shoes.

#### *Morocco and Dyed Sheep-skin Leather, &c.*

Morocco and dyed sheep-skin leathers are represented by thirty-one Exhibitors from Paris, London, Leeds, Mayence, Barcelona, Tana, and Turkey. This description of leather is tanned with the leaves of the sumach tree (*Rhus coriaria*), imported into this country from the island of Sicily. Great excellence has been attained in

the manufacture, both in the brilliancy and variety of colour, especially when it is considered that neither strong acid, nor great heat, can be applied without danger of destroying the fibre of the leather.

The specimens of morocco from Turkey, Tunis, and Egypt, show the manufacture in its origin, and no alteration appears to have taken place in the mode of dyeing, &c., since the period when western Europe was indebted to them for this manufacture. The red morocco of Turkey and Egypt is brilliant and permanent, and though well suited for their particular use, is not adapted for general consumption.

BEVINGTONS and SONS, Neckinger Mills, London (1, p. 518), exhibit an assortment of morocco leather, enamelled seal skins, Cape sheep, kid, and gloving leather, and a series of the materials used in tanning and leather-dressing, to illustrate the several modes of curing and tanning practised in this country. They also exhibit skins in the unmanufactured state, and a Macedonian lamb skin divided to show the natural laminations by which the epidermis, the rete mucosum, and cutis, are easily distinguished.

The Jury award Prize Medals to the following Exhibitors:—

BAYVET BROTHERS and Co., 16 Rue Mauconseil, Paris (415, France, p. 518), for an assortment of morocco, roan, and calf leather, finished with great regularity, and in a variety of beautiful colours. The cochineal red and the various shades of green morocco, are remarkable for the fullness of colour. The black morocco is also of good quality.

ENMERICH and GOERGER, Strassbourg (1212, France, p. 1235), for a good assortment of coloured and black morocco, well dyed and manufactured.

WILSON, WALKER, and Co., Leeds (11, p. 518), for a very large assortment of coloured sheep, morocco, and calf leather, well manufactured, and adapted, from their price, for general consumption.

The Jury make Honourable Mention of the following Exhibitors:—

DAVID, C., 12 Rue Mauconseil (812, France, p. 1219), for a beautiful collection of dyed morocco, for book-binding.

DELISLE and Co., Grenoble (1181, France, p. 1234), for specimens of sheep and morocco leather, printed in permanent colours, for furniture, &c.

DEED, J. S., Little Newport Street, London (10, p. 518), for a good assortment of morocco leather, for furniture and bookbinding.

EAST and SON, Bermondsey, London (34, p. 519), for dyed and embossed sheep leather, in imitation of Utrecht velvet. This appears to be a good appropriation of leather which is imperfect in the grain, and is manufactured with skill and good taste.

GEORGE CLEMENT, 102 Dean Street, Westminster (32, p. 519), for good specimens of morocco and Russian leather, adapted for furniture and bookbinding.

GEORGE, JOSEPH, 81 Dean Street, Westminster (289, p. 529), for specimens of leather, beautifully gilded, embossed, and painted.

GIRAUD BROTHERS, Paris (850, France, p. 1220), for dyed morocco and sheep leather, in brilliant and permanent colours.

LUTWICHE and GEORGE, Skinner Street, London (53, p. 520), for well-manufactured morocco leather and dyed sheep-skin rugs.

ROEG, SALVADOR, Barcelona (249B, Spain, p. 1345), for an assortment of morocco leather, dyed in a variety of colours, for shoes; and for well-manufactured black morocco.

#### *Alum and Gloving Leather.*

Alum, or white, leather is manufactured principally for the purposes of the glove-maker, and is represented in the Exhibition by twenty contributors.

The common method of making this description of leather is to immerse the prepared skin in a solution of alum and salt, in equal proportions; but where elasticity

and softness are required, as for kid gloves, very much care and attention are necessary. The skin, having been first softened in lime-water, has to be many times washed, and worked in pure water, and afterwards in fermented bran-liquor. Yolks of eggs, flour, alum, and salt, are the materials with which the skin is made into soft leather: and it is then dried, worked over a round blunt knife, and, after a second washing and softening with yolks of eggs, it is ready to receive from the dyer the beautiful colours, so well known to the public, in the manufactured article of gloves. It has been estimated that 6,000,000 of eggs are annually consumed in the glove-leather manufactories of France and England.

A few specimens of the excellent kid leather of France are exhibited by M. JOURVIN, of Paris: these skins are manufactured at Annonay, a town about fifty miles south of Lyons. The great superiority of the manufacture of this place is very remarkable, and a very large portion of the kid skins from every quarter of the globe are sent thither to be converted into gloving leather. Though the supply is derived principally from the adjacent provinces of France, from Italy, Switzerland, and Germany, yet Ireland and the East Indies have of late years contributed no inconsiderable quantity. The total number annually manufactured there is not less than 4,000,000 skins.

It is worthy of remark also, that a very large portion of the lamb skins, suitable for gloving leather, are sent from many countries to be manufactured at Yeovil, in Somersetshire, and the adjacent neighbourhood. It is not unusual to see in that place the lambs' skins of Italy, Austria, Spain, Turkey, Denmark, Bordeaux, Buenos Ayres, and the Cape of Good Hope. The climate and the peculiarities of water, which are so admirably adapted for kid leather-dressing in France, are unsuited to the proper manufacture of lamb skins, which require a more temperate climate, and other facilities of manufacture, which are met with in England.

The following Exhibitors have been awarded Prize Medals:—

**BARRANDE, J. P.**, Rue du Fer à Moulin, Paris (756, France), for an assortment of dyed goat, sheep, calf, and kid leather, in variety of colours. The bronze colour of this manufacturer is excellent and durable; and the softness of the tanned calf leather renders it admirably adapted for the upper part of boots.

**CORRY, J. and J.**, Queen's Camel, Somersetshire (314), for Italian lamb skins, dressed and dyed in a variety of colours, for gloves.

**LOLAGNIER, —**, 6 Rue St. Hippolite, Paris (1330, France), for specimens of kid, lamb, calf, and sheep leather, suitably manufactured for gloves.

The Jury make Honourable Mention of the following Exhibitors:—

**BOULOGNE, P.**, Prague (334, Austria, p. 1023), for kid and lamb-skin leather, dressed for gloves, in which the smoothness and strength of the grain have been well preserved.

**LUXEMBURG GLOVE MANUFACTORY** (4, p. 1130), for bronze and black kid leather, and for specimens of dyed kid and lamb leather, for gloves.

**MATTAT and SONS**, Randers (10, Denmark, p. 1356), for very well-dressed leather, both for white and tanned gloves.

**RANNIGER, J. L. and SON**, Altenburg (741, Prussia, p. 1091), for an assortment of lamb leather, dyed a variety of colours, for gloves.

#### *Oil or Chamois Leather.*

There are fourteen Exhibitors of chamois leather, of whom four are English manufacturers, two French, and eight of other countries.

The peculiar quality given to leather by the process of the oil or chamois leather manufacturer is extreme softness, which renders it a suitable article for gloves, and many other uses where this quality is required.

It is manufactured by the continued application of oil

to the skin, alternately with a process of beating in fulling mills, and exposing to the air for partial drying. In about ten repetitions of the oiling and drying process the skins are sufficiently saturated, and are allowed to remain in tubs until they become hot by natural fermentation, after which they are washed in a strong alkali, and a most perfect and useful kind of leather is formed.

So recently as the commencement of the present century sheep skins manufactured in this mode were extensively employed as clothing; but woollen cloth has gradually superseded their use, and the trade has considerably declined in consequence.

The Jury award Prize Medals to the following Exhibitors:—

**PULLMAN, R. W. and J.**, 17 Greek Street, Soho, London (285, p. 529), for an assortment of buck, doe, and chamois leathers of every description, very perfectly manufactured, for a variety of purposes.

**TEXIER, junior**, Niort (1033, France, p. 1228), for specimens of buck, doe, and fawn leather, and for some well-dressed chamois sheep leather, stained in a variety of colours for gloves.

The Jury make Honourable Mention of the following Exhibitors:—

**LAYDET and Co.**, glove manufacturers, Paris (296 France, p. 1191), for specimens of chamois leather, dyed in suitable colours for gloves. (Awarded a Prize Medal by the Jury of Class XX.)

**RANDALL and DICKS**, Greek Street, Westminster (284, p. 539), for a well-manufactured assortment of buck, doe, and chamois and gaiter leather. These Exhibitors show the application of chamois leather in the pianoforte, where it is used to stop the prolonged vibration of the wires.

#### *Dyed Sheepskin Rugs, &c.*

There are thirteen Exhibitors of dyed rugs manufactured from English sheep and Angora goat skins. Though the manufacture is of recent origin in this country, it appears to have been known to the Eastern nations in the most remote times. In the Old Testament, the "ram skins dyed red" are mentioned, Exod. xxvi. 14, as ornaments for the tent of the Holy Tabernacle. The sheep skins of England, especially the coarse wool skins of Lincoln and Leicestershire, are more adapted for this purpose than those of any other country, on account of the peculiar lustre of the wool. These rugs are extensively used in Great Britain for door-mats, and are exported to America and the continent of Europe. The excellence of the manufacture consists in the perfect extraction of the natural grease, in making them complete leather with alum and sumach, and in dyeing the wool permanent and bright colours.

The Jury award Prize Medals to the following Exhibitors:—

**BEVINGTONS and MORRIS**, 67 King William Street, London (332, p. 535), for an assortment of sheep-skin rugs, in great variety of colours. These Exhibitors show bordered rugs of several designs, in good taste; and Angora goat skins, manufactured in a similar manner.

**CLARKE, C. and J.**, Glastonbury (48, p. 520), for sheep and lamb skin rugs, dyed and manufactured into a variety of useful articles.

**DEED, J. S.**, Little Newport Street, Westminster (10, p. 518), for Angora goat and English sheep skin rugs dyed in many beautiful colours.

The Jury make Honourable Mention of the following Exhibitors:—

**ROOD, G. and Co.**, Bolton Borough, Glastonbury (49, p. 520), for hearth rugs made from dyed Angora goat skins, and for varieties of door-mats manufactured from English sheep and lamb skins.

**WINSON and SON**, Hermandsey, London (14, p. 518), for a good assortment of dyed sheep skin rugs, skins for cavalry saddles, and several manufactured articles.

*Vellum and Parchment.*

Parchment is prepared from sheep skins by the simplest process. After the skin has been steeped in lime and water it is stretched in a frame, and by repeated working with hot water, and several applications of whitening which are dried in the sun, the skin is entirely cleansed from the grease. It is brought to a fine surface by skilful labour with a round sharp knife, and when dry is fit for use.

Vellum is made from calf skins prepared in a similar manner.

This manufacture is represented by seven Exhibitors.

The Jury award Prize Medals to the following Exhibitors:—

BERTHAULT, Issodon (56, France, p. 1174), for a very complete and extensive assortment of parchment and vellum, applicable for deeds, bookbinding, tambourines, and for the machinery of spinning-mills.

LEVER, J. and J., 13 Size Lane, London (24, p. 519), for specimens of vellum and parchment, manufactured for bookbinding, deeds, and tambourines. These Exhibitors show some well-dyed vellum, and other samples adapted for paintings.

The Jury make Honourable Mention of the following Exhibitors:—

EVANS and SON, 10 Silver Street, London (18, p. 518), for specimens of well-manufactured parchment, and for direction-labels, very completely made from the same material.

SÖDERMANN, W., Erfurt (743, Prussia, p. 1091), for vellum and parchment of extreme whiteness, prepared for deeds, drum-heads, and for machine or cylinder parchment.

*Saddlery, Harness, and Portmanteaus.*

In reporting on saddlery, harness, and portmanteaus, the Jury remark, that the general character of the articles is highly creditable to the Exhibitors, and show that considerable skill and ingenuity are devoted to this department of industry. There are upwards of 120 Exhibitors in this subdivision.

From the nature of the manufacture it is less concentrated in particular localities than most others. There is no town of note in England where one or more of the trade does not find ample occupation; and as the manufactured article continually falls into the hands of distant makers for repair, the knowledge and inventions of one manufacturer are quickly circulated through a wide district. Hence we find considerable uniformity and excellence of manufacture in this department.

The chief endeavour of the saddler and harness-manufacturer is to obtain strength, with lightness and convenience of form; for which purpose the strongest kinds of leather are used in combination with iron, wood, and other materials. Walsall, in Staffordshire, is the principal seat of the wholesale trade, where considerable quantities of saddlery and harness are prepared for exportation. Great ingenuity and invention have been displayed in the numerous varieties of types, of which there are very many sorts known to the trade.

The necessity of making of the saddlery of other countries by a very different standard from our own is evident; the form of saddle, for instance, that is well adapted for our smooth roads and well-trained horses, would be very inefficient in the mountainous districts of Spain and South America.

The Jury have had their attention called to some portmanteaus, of very ingenious and clever construction, which, from the facilities they afford the traveller of rapid arrangement and convenience of access, will promote the comfort of a very numerous class of the community.

The Jury award Prize Medals to the following Exhibitors:—

Boston (408, United States, p. 1155), for

BLACKWELL, S. and R., 256 Oxford Street (78, p. 521-2), for phaeton harness of patent black leather. The mountings are in good taste; the materials and workmanship are also of good quality.

BLYTH, R., 4 Park Lane, Westminster (90, p. 522), for a lady's saddle, well manufactured; and a hunting or park saddle, with improved elastic seat.

BRACE, H., Walsall, Staffordshire (58, p. 520), for two cases of bits, stirrups, and spurs, for the South American market.

BROWN and SON, Birmingham (65, p. 521), for specimens of saddle-trees, with whalebone springs, galvanized plates, &c., to prevent corrosion.

CAISTER, A. B., 7 Baker Street, Westminster (77, p. 521), for well-manufactured hussar and hunting saddles, with pair of harness pads.

COOPER, M., York (51, p. 520), for a case of saddlery, containing articles of very superior workmanship: the racing saddle, in particular, weighing only two pounds, is remarkable for its neat manufacture.

CUFF, R. 18 Cockspur Street, London (96, p. 523), for an embroidered velvet saddle, riding bridle, and harness, manufactured with much taste and elegance.

EARNshaw, H., 91 Wimpole Street, London (107, p. 523), for a case of harness, containing blue morocco and other bridles, well manufactured.

HICKEY and TULL, Philadelphia (58, United States, p. 1437), for two portmanteaus, well arranged and strongly constructed.

KANE, G., Dublin (62, p. 521), for portmanteaus and camp furniture, so ingeniously contrived, that most of the articles required to furnish an officer's apartment are contained in a travelling chest.

LACEY and PHILLIPS, Philadelphia (41, United States, p. 1435), for a case of harness, in which the mountings are of solid silver; the materials are of excellent quality and the workmanship very elaborate.

LADOUER LE JEUNE C., Brussels (256, Belgium, 1159), for saddlery and harness manufactured in excellent style, with good materials and workmanship.

LANGDON, W., junior, 9 Duke Street, London (89, 522), for a light phaeton harness, constructed of the best materials, and well adapted for its intended use.

LAST, S., 256 Oxford Street, London (38, p. 519), for well-contrived railway portmanteau, divided into five compartments, to facilitate the access to any articles contained in it.

MIDDLEMORE, W., 31 Holloway Road, Birmingham (67, p. 521), for a lady's embroidered saddle, and another with elastic seat; also for a new mouthing rein for unbroken horses, &c., the whole well manufactured.

MORRIS, R., Montreal (113, Canada, p. 965), for a set of double sleigh harness, of excellent material and workmanship.

PASSMORE, W., 27 Little Windmill Street, Westminster (79, p. 523), for a set of single horse harness: the style and workmanship are in every respect superior.

POLLOCK, J., Glasgow (379, p. 523), for a very perfect set of Scotch harness.

PRAX and LAMBIN, Paris (688, France, p. 1211), for a large and varied collection of saddlery and harness; many of the articles are elegantly designed, and the materials have been well selected.

SWAIN and ADAMS, 185 Piccadilly, London (82, p. 523), for a large assortment of whips and canes, showing much taste in the manufacture, and superiority of workmanship.

WHITE, J. C., 29 Liverpool Street, London (86, p. 522), for silver-mounted harness with improved registered tag. A very useful and ingenious invention.

The Jury desire to make Honourable Mention of the following Exhibitors:—

ADAMS, H., New York (475, United States, p. 1155), for a portable saddle ingeniously constructed.

ALFORD, W., and G., Birmingham (64, p. 521), for specimens of whips of various patterns, well manufactured.

BARTON, E., Walsall (56, p. 520), for a

BELL, C., 34 Wigmore Street, London (93, p. 523), for a lady's saddle and single harness.

BYWATER, W. M., 99 Piccadilly, London (94, p. 523), for harness and improved Russian cavalry bridles.

COWAN, L., Barrhead, New Paisley (273, p. 528), for a very good set of Scotch cart harness of patent leather.

HUDSON, S., Dublin (80, p. 520), for a hunting-saddle with elastic seat, and a side-saddle with safety stirrups.

HUGHES, R., Clifden Street, Finsbury, London (106, p. 523), for heraldic mountings for harness.

MAXWELL and Co., 161 Piccadilly, London (52, p. 520), for socket spurs in various stages of manufacture.

PENNY, J., 37 Union Street, Middlesex Hospital, London (91, p. 522), for a state pony bridle, designed by W. H. Rogers, made by W. Langdon.

STEWART, W., Toronto (134, Canada, p. 966), for a set of single sleigh harness, made of varnished leather.

The Jury desire to record their great obligations to the undernamed gentlemen :—

Mr. Thomas Powell, leather factor, Lime-street

Mr. William Hackblock, Rood lane.

Mr. Frederick Dandleker, Hambetikon, Lake of Zurich.

Mr. Martin Blackmore, Bread Street, London.

Mr. E. W. Roberts, Page's Walk, Bermondsey.

Mr. Alfred Rymer, Nassau Street, Westminster.

Mr. M. Nicholls, Little Windmill Street, Westminster.

Mr. George Kent, Mornington Crescent, Westminster.

Mr. George Kidd, Associate Juror, 257 Oxford-street.

All of whom have very freely given their valuable services in the examination of many of the Exhibitors' goods, on the merits of which they were peculiarly qualified to assist the Jury in forming a correct judgment.

J. A. NICHOLAY, }  
J. B. BEVINGTON, } REPORTERS.

London, December, 1851.

## CLASS XVII.

## REPORT ON PAPER AND STATIONERY, PRINTING AND BOOKBINDING.

[ The figures after the Names (between parentheses) refer to the Exhibitors' Numbers and to the Pages in the OFFICIAL DESCRIPTIVE AND ILLUSTRATED CATALOGUE. ]

## Jury.

STYLVAIN VAN DE WEYER, *Chairman*, Belgium; Envoy Extraordinary and Minister Plenipotentiary from H. M. the King of the Belgians.

THOMAS DE LA BEE, *Deputy Chairman*, 84 Westbourne Terrace, Hyde Park: Ornamental Stationery Manufacturer.

CHARLES WHITTINGHAM, *Reporter*, Chiswick, and Took's Court, Chancery Lane; Printer.

A. FIRMIN DIDOT, *Joint Reporter*, France; Member of Central Jury, &c.\*

Professor HULSE, *Zollverein*; Director of the Royal Polytechnical Academy at Dresden.

VISCOUNT MAHON, F.R.S., 41 Grosvenor Place.

HENRY STEVENS, *Barnet*, Vermont, United States; residing at Morley's Hotel, London.

CHARLES VENABLES, *Plomer Hill House*, High Wycombe; retired Paper Manufacturer.

The articles which the Jury had to examine were classified in the following manner:—

- A. Paper in the Raw State as it leaves the mill.
- B. Articles of Stationery
- C. Pasteboards, Cards, &c.
- D. Paper and Scaleboard Boxes (*cartonnerie*).
- E. Printing (not including *Fine Art Printing*).
- F. Bookbinding.

The Jury met on the 17th of May, and continued their labours till the 28th of July, when their awards were finally settled and transmitted to the proper authorities.

They did not think it necessary to divide themselves into sub-committees; but in adjudicating upon the specimens of printing intended for the use of the blind, they requested the assistance of George Sumner, Esq., of the United States, and William Hughes, Esq., of Henshaw's Blind Asylum, Manchester, to which request these gentlemen kindly acceded.

The first duty of the Jury was to refer to the "Decisions regarding Juries," and afterwards to the "Instructions from the Council of Chairmen," in which, among other conditions, it is stated that "a classified list of the subjects under the province of each Jury is prepared, and forms the limitation of each class;" and that "those articles will be rewarded which fulfil in the highest degree the conditions specified in the Sectional List," namely:—

"Increased usefulness, improved form, superior quality, or superior skill in workmanship, new use of known materials, use of new materials, new combination of materials, beauty of design in form or colour, or both with reference to utility, the cheapness with reference to production, and that the Report should describe the state of industry as shown in this Exhibition."

The Jury, in accordance with the foregoing instructions, proceeded to the examination of the different articles. The classified list of subjects was found to be very defective, the classification only extending to English Exhibitors, and many articles were found to be misplaced in the classes to which they had been assigned. The Jury had thus to refer several articles to their proper classes, and to decide that maps did not come under their consideration, though several had, in the Official Catalogue, been inserted in Class XVII.; that the lithographic colour

press, as well as all other machinery, came under the jurisdiction of Class VI., the Jury offering at the same time to give their assistance and opinions individually or collectively, should any such assistance or opinions be desired; that they could take cognizance neither of literary merit, as had been required of them, nor of different philological systems of printing, as phonetic printing, phototypy, phonography, &c. &c.; and lastly, that several specimens of calligraphy and penmanship had erroneously been sent to them.

With regard to the Foreign Department the Catalogue was still more imperfect; and the Jury had to search out the articles which appertained to their Class. It is greatly to be feared that, notwithstanding all the care taken by the Jury, there may be articles which have escaped their observation.

It will be observed that the Jury, in strict conformity with the principles laid down by the Royal Commission, have only recommended one Council Medal, and that for typography; not that they did not recognize the excellence and beauty of many of the specimens exhibited, and the skill and perfection which, in many points, the art of printing displayed, but because there did not appear to be any production so clearly bearing the character of *novelty of invention or new application of a known principle* as to justify such a recommendation, with the exception of the products of the Imperial Court and Government Printing Office of Vienna, which presented both novelty of invention and a number of new combinations in the art of typography.

No prize was awarded to publishers, as such, notwithstanding the merit of their publications.

Until recently, bookselling had not been represented at the Exhibitions of Industry: the instructions given to the Jury of the Great Industrial Exhibition of all Nations did not assign to it any distinct position; and, therefore, in the different countries the booksellers have refrained from sending their publications, not deeming that their trade, connected more or less closely as it is with the sciences and with letters, could be looked upon as a branch of industry.
